UNISA Economic Research Working Papers constitute work in progress. They are papers that are under submission or are forthcoming elsewhere. They have not been peer-reviewed; neither have they been subjected to a scientific evaluation by an editorial team. The views expressed in this paper, as well as any errors, omissions or inaccurate information, are entirely those of the author(s). Comments or questions about this paper should be sent directly to the corresponding author.

FINANCIAL INTERMEDIARIES, CAPITAL MARKETS, AND ECONOMIC GROWTH: EMPIRICAL EVIDENCE FROM SIX COUNTRIES

Sheilla Nyasha¹ and Nicholas M. Odhiambo

Abstract

This paper investigates the dynamic causal relationship between financial systems and economic growth in three developing countries – South Africa, Brazil and Kenya – and three developed countries – the United States of America, the United Kingdom and Australia – during the period from 1980 to 2012. The study includes both bank-based and market-based financial systems. The study includes savings as an intermittent variable – thereby creating a trivariate Granger-causality model. The method of means-removed average is employed to construct bank- and market-based financial development indices. Using the ARDL bounds testing approach, the empirical results of this study reveal that the causality between financial systems and economic growth is indistinct; and it varies widely across countries and over time. Overall, the study finds that there is a long-run causal flow from bank-based financial development to economic growth in the UK and Australia; a distinct feedback loop in the case of Brazil; and a neutrality relationship in the case of Kenya, South Africa and the USA. For market-based financial development, the study finds evidence of bidirectional causality in the case of Kenya; a demand-following hypothesis in South Africa and Brazil; and a neutrality relationship in the case of Australia and the UK. The study, therefore, repudiates the traditional argument, which contends that the finance-growth nexus follows a supply-leading phenomenon.

Keywords: Bank-Based Financial Development, Market-Based Financial Development, Stock Market, Banks, Economic Growth, Granger-Causality, USA, UK, Australia, South Africa, Brazil, Kenya

1. Introduction

Even though the relationship between financial development and economic growth has been extensively studied, the debate between financial development – both bank-based and market-based – and economic growth, has been on-going for some time, yet with little consensus. Four views exist in the finance-growth causality literature. The first and predominant one is the “supply-leading hypothesis”; this is also known as the “finance-led growth hypothesis”. This view claims that financial development is important; and it leads to economic growth (see, among others, McKinnon, 1973; Shaw, 1973; King and Levine, 1993a).

The second view is the “demand-following hypothesis” or the “growth-led finance hypothesis”, which postulates a causal flow from economic growth to financial development. It is this view that considers bank-based and market-based financial development to be demand-driven (see also Robinson, 1952; Gurley and Shaw, 1967; Goldsmith, 1969; Jung, 1986).

The third view is the “feedback hypothesis” or the “bidirectional-causality view”, as it is also known. The feedback hypothesis assumes a positive two-way causal relationship between financial development and economic growth. Thus, this view ascribes equal importance to both the financial and real sectors of the economy (see Patrick, 1966). Then, there is the fourth and unpopular view, which suggests that financial development and economic growth are not causally related; and that neither of the two sectors has a significant effect on the other (see also Lucas, 1988; Graff, 1999).

These are the conflicting arguments, supported by varying views, which necessitate further research on the finance-growth causality topic. Furthermore, the bulk of the existing studies on the causality between financial development and economic growth is mainly

concentrated in Asia, Latin America and in selected developed countries. Specific studies addressing the causal link between financial development and economic growth in developing countries, especially those in sub-Saharan Africa, are very scant. Even where these studies exist, only a handful of them have compared the casual links between financial development and economic growth in developing countries with the links in the developed countries.

Despite the availability of an extensive global pool of empirical work on this subject, very few studies have been conducted on the causality between bank-based financial development and economic growth, on the one hand; and between market-based financial development and economic growth on the other hand. Until recently, most studies on the finance-growth nexus have relied only on bank development, as a proxy for financial development; without paying specific attention to any particular segment of the financial system. Yet, it is now well-known that a financial system is made up of both bank-based and market-based segments.

Additionally, the majority of the studies, which have examined the causality between financial development – bank- or market-based – and economic growth, have over-relied on a bivariate framework; although it is now known that the results of the bivariate causality test may be invalid, due to the omission of important variables affecting both financial development and economic growth in the causality model (Odhiambo, 2009a). The introduction of additional variables into the causality framework might not only alter the direction of causality; but it could also affect the magnitude of the estimates (see also Loizides and Vamvoukas, 2005; Odhiambo, 2009a).

Against this background, the current study attempts to investigate the causal relationship between bank-based financial development and economic growth, on the one hand; and between market-based financial development and economic growth, on the other hand, in three developing countries – South Africa, Brazil and Kenya – and three developed

countries – the United States of America (USA), the United Kingdom (UK) and Australia. The study also aims to compare the causality results of the two country groups. Thus, these countries have been selected; so as to enable the conducting of parallel studies on countries at different stages of development. The availability of long-term historical time-series data, especially stock market data, also prompted the selection of these six countries. Overall, the selection is a modest representation of economies prevailing in both the developing and the developed parts of the world. The study is conducted within a trivariate Granger-causality setting, using the newly developed ARDL bounds testing approach.

The rest of this paper is organised as follows: Section 2 gives an overview of the financial sector reforms in the study countries; while Section 3 reviews the literature on the linkages between bank-based financial development and economic growth, and between market-based financial development and economic growth. Section 4 presents the empirical model specification, the estimation techniques, and the empirical results. Section 5 concludes the study.

2. Financial sector reforms and development in the study countries

By any standard, modern or otherwise, the USA, the UK and Australia have highly developed financial systems, which rank very highly in terms of the development and sophistication of their financial institutions and financial markets – as well as the size, depth and access to their financial services. This group of countries has more advanced financial systems than its developing country group counterparts, except for South Africa, which has a financial system that compares well with those in the developed countries. Although Kenya and Brazil's financial systems are behind those of the developed countries and that of South Africa, Kenya's financial system is regarded as one of East Africa's largest and most developed; while the Brazilian financial system is the largest and most sophisticated in Latin America (World Bank, 2007).

While the Kenyan financial system is generally referred to as a bank-based financial system, because of its bank-activity prominence, the other five study countries' financial systems are generally referred to as market-based financial systems; since these financial markets share centre stage with banks in driving economic growth in these countries (see Demirguc-Kunt and Levine, 2001). Of the six countries in this study, the USA has the highest number of banks, followed by the UK, and then Australia. Behind Australia, there is Brazil; and this is followed by South Africa, and then Kenya.

From the stock market side, among the developed countries under study, the USA has the highest number of big stock exchanges; while it is Brazil that has the highest number of stock exchanges from the developing-country group. The UK and Australia have one major stock exchange each; but Kenya and South Africa each only have one stock exchange.

As with any other country, the study countries have undergone a series of financial sector reforms over the years, aimed at modernising their financial systems to match the increasing demand for development. In the developed countries, these reforms kicked off in the first half of the 20th Century; with the developing countries only joining towards the end of the second half of the same century. Although these reforms varied from country to country in terms of scope, intensity and approach, they were aimed at achieving common goals. From the bank-based segment of the financial sector, these reforms have concentrated on improving the legal, regulatory, judiciary and supervisory environments; facilitating financial liberalisation; restoring bank soundness; and rehabilitating the financial infrastructure.

These reforms have also included programmes designed to encourage new entrants (Central Bank of Brazil, 2009; FSD Kenya, 2010; International Monetary Fund, 2011; Federal Deposit Insurance Corporation, 2012; Bank of International Settlement, 2012; Australian Banking Reforms, 2013). On the stock market side, the reforms have focused on addressing the legal, regulatory, judiciary and supervisory aspects of the financial market business. In

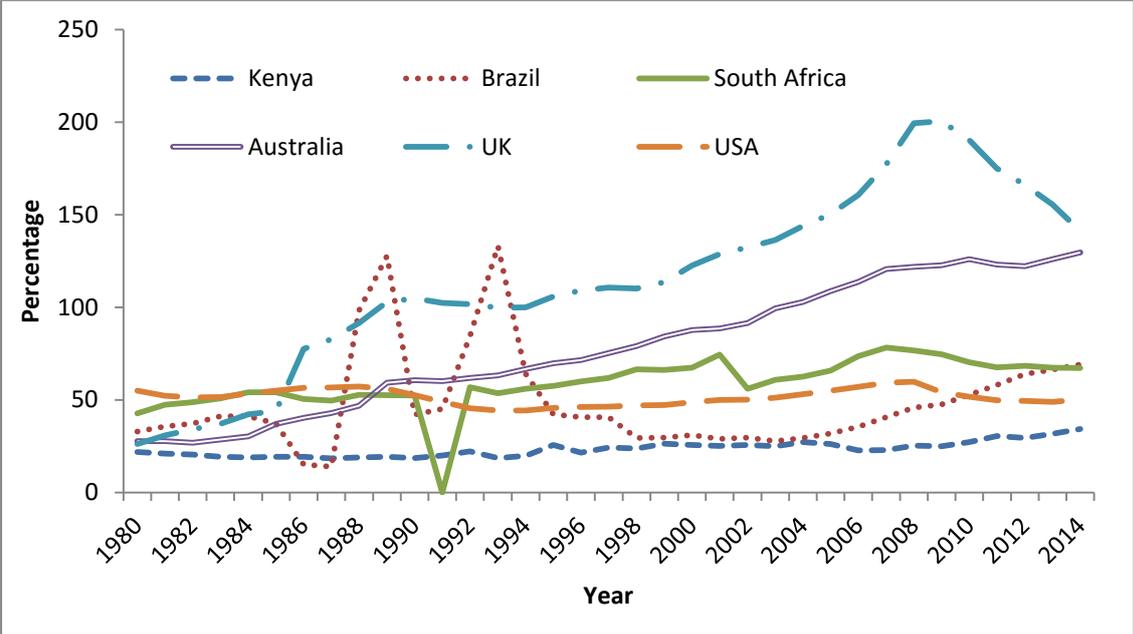

addition, these reforms have also focused on the general modernisation of the trading environment.

Although all the countries under study have responded positively to the reforms, the speed and magnitude of this positive response has differed from one country to another, because of the differences in initial country conditions, approaches and consistency in driving the reforms. Overall, the rigorous reforms over time have given rise to a developed and well-regulated financial system in the developed countries, as well as South Africa; with Brazilian standards trailing behind those of South Africa; and the Kenyan standards trailing behind the Brazilian developmental standards.

The development of the bank-based segments of the financial systems in the countries of study is demonstrated by the growth in private sector credit, the increasing number of Automated Teller Machines (ATMs), the strong legal rights, as well as decreasing levels of non-performing loans (see World Bank, 2015). On the other hand, the development of the market-based segments is shown by an increased number of listed companies, an increase in stock market capitalisation, total value traded, and the turnover ratio up to the early 2000s (World Bank, 2015).

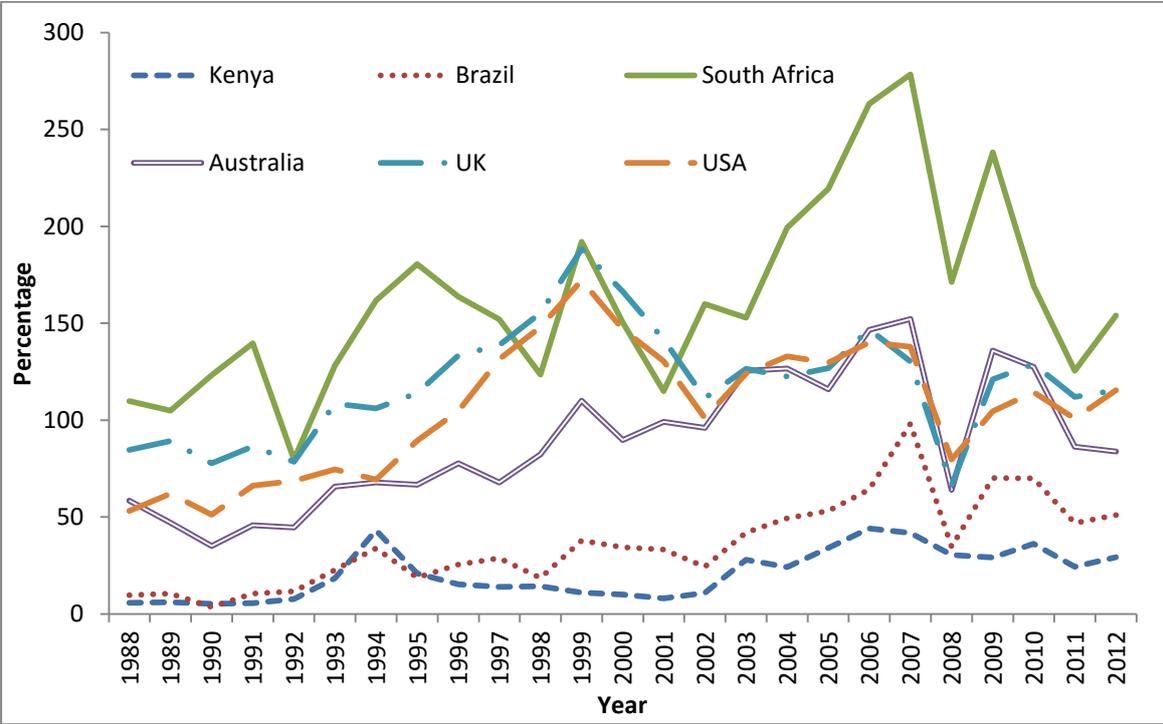

Overall, Kenya has relatively the smallest stock market – in terms of the number of listed companies, stock market capitalisation, the total value of stocks traded and turnover ratio – while the USA has the biggest and the most-liquid stock market in general. Figure 1 illustrates the trends in banking-sector growth, as measured by credit extension to the private sector in the six study countries during the period 1980 - 2014. Figures 2 - 4 depict and compare the trends in stock market development in the six countries during the period 1988 to 2012.

Figure 1: Trends in the Banking Sector Growth in the Six Countries (1980-2014)

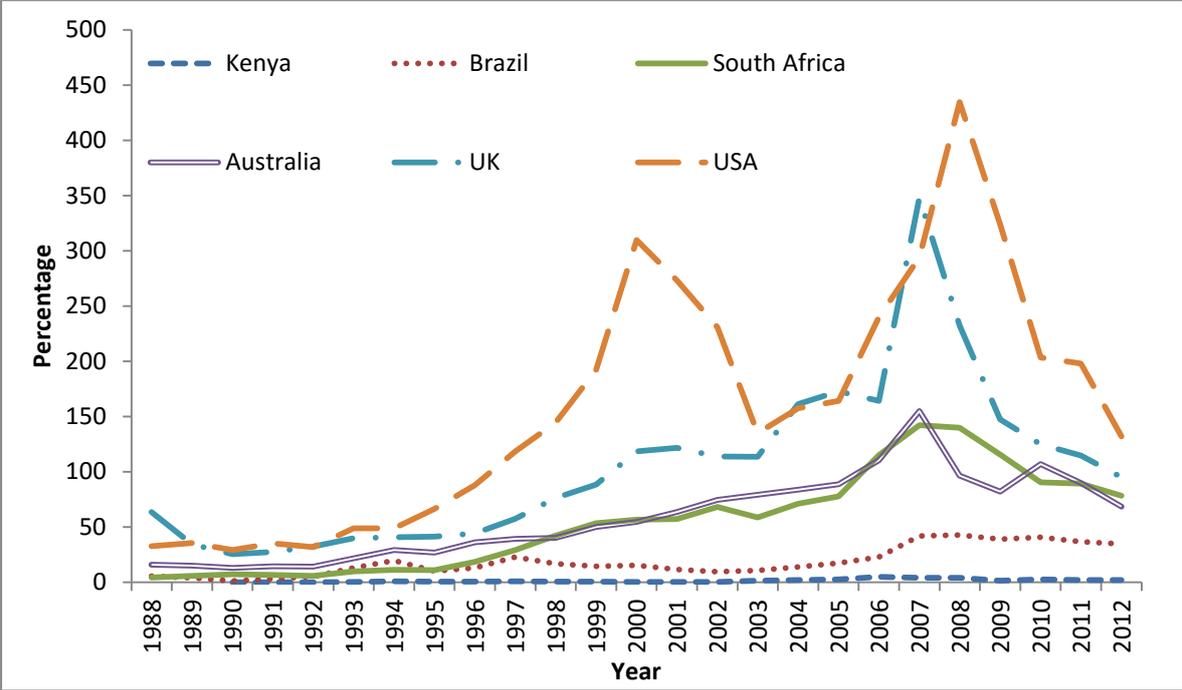

Source: World Bank Development Indicators (2015)

Figure 2: Trends in Stock Market Capitalisation in the Six Countries (1988-2012)

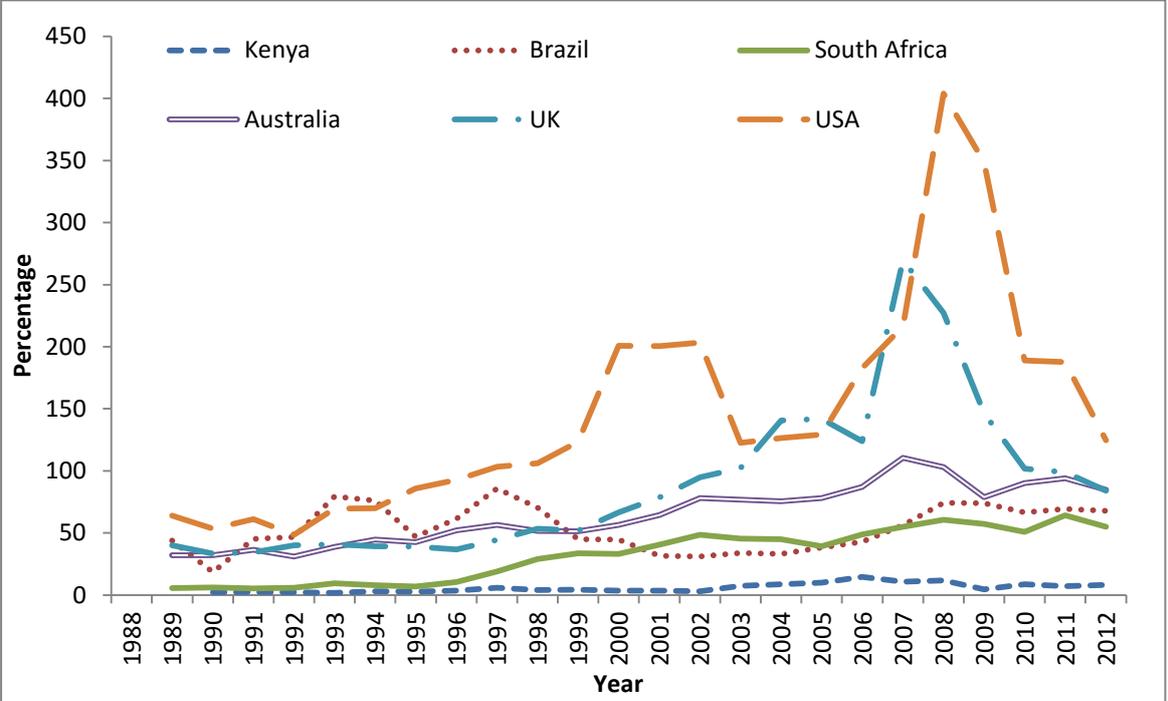

Source: World Bank Development Indicators (2015)

Figure 3: Trends in Total Value of Stocks Traded in the Six Countries (1988-2012)

Source: World Bank Development Indicators (2015)

Figure 4: Trends in Turnover Ratio of Stocks Traded in the Six Countries (1988-2012)

Source: World Bank Development Indicators (2015)

Despite this growth, these countries' financial systems still face some challenges. Although these challenges differ in dimension and magnitude, financial stability and Eurozone contagion seem to top the list among the developed countries; while financial inclusion, reduced bank profitability and stock market liquidity, seem to top the list among the developing countries.

3. Bank-based financial development, market-based financial development and economic growth

The debate regarding the direction of causality between financial development and economic growth has been ongoing since the 19th Century (see Bagehot, 1873). The thrust of the debate centres on whether it is bank-based and market-based financial development that drives economic growth or vice versa. To date four views exist in the literature regarding the relationship between financial development – whether bank-based or market-based – and economic growth.

The first view is the “finance-led growth hypothesis” or the “supply- leading hypothesis”. The supply-leading hypothesis argues that financial development is important and leads to economic growth. This view has recently been widely supported by McKinnon (1973), Shaw (1973), and King and Levine (1993b), among others. Although Schumpeter (1911) is generally acknowledged as the first proponent of the supply-leading theory, the support for the supply-leading response can be traced as far back as Bagehot (1873) who claimed that the financial sector played a major part in the growth process in England by enabling the mobilisation of capital for immense works. It is this view that was reinforced by

Schumpeter (1911), when he argued that finance leads economic growth and that financial institutions are necessary for a capitalistic economy's development.

The second view is the “growth-led finance hypothesis” or the “demand-following hypothesis” put forward by Robinson (1952) in his attempt to challenge Schumpeter’s view. He argued that it is the development of the real sector which leads the development of the financial sector and that where there is economic growth, financial sector development follows (Robinson, 1952). Gurley and Shaw (1967), Goldsmith (1969) and Jung (1986) also lend support to this line of argument.

The third view is the “bidirectional causality view”, argued for by Patrick (1966). Patrick attempted to reconcile the two conflicting theories by arguing that the direction of causality between financial development and economic growth changes over the course of development, a phenomenon commonly known as “the Patrick’s Hypothesis”. Thus, according to Patrick (1966), the supply-leading pattern dominates during the early stages of economic development while the demand-following pattern dominates at later stages.

Then there is the fourth view, though unpopular, commonly known as the “the independent hypothesis” that suggests that the role of financial development in driving economic growth is exaggerated, and that there is no causal relationship between the two. Despite being there four competing views on finance-growth causality, for a long time now, the conventional wisdom has been in favour of the supply-leading response, where the development of the financial sector is expected to precede that of the real sector (see Odhiambo, 2008).

The supply-leading hypothesis has found support from studies on bank-based financial development and economic growth; as well as those on market-based financial development and economic growth. From the bank-based financial development and economic growth front, these studies include: Beck and Levine (2002), Christopoulos and Tsionas (2004), Odhiambo (2009a) and Akinlo and Egbetunde (2010). On market-based financial development and economic growth, these studies include those of Choong *et al.* (2005); Adjasi and Biekpe (2006); Deb and Mukherjee (2008); Akinlo and Akinlo (2009); Osuala *et al.* (2013); and Bayar *et al.* (2014).

The demand-following hypothesis has also found support in the finance-growth causality literature. Studies on the causality between bank-based financial development and economic growth that support this view are those of Odhiambo (2004), Ang and McKibbin (2007), Odhiambo (2009b), and Akinlo and Egbetunde (2010), among others. From the market-based financial development and economic growth side, studies by Shan *et al.* (2001), Shan and Morris (2002), Akinlo and Akinlo (2009) and Athanasios and Antonios (2012) support the demand-following hypothesis.

From the bank-based financial development and economic growth side, the feedback response is supported by the following studies, among others: Wood (1993), Akinboade (1998), Abu-Bader and Abu-Qarn (2008) and Akinlo and Egbetunde (2010). On the other hand, Arestis and Demetriades (1997), Hondroyiannis *et al.* (2005), Carp (2012), Cheng (2012) and Marques *et al.* (2013), among others, support the bidirectional causality from the market-based financial development and economic perspective.

Finally, the unpopular view that bank-based and market-based financial development and economic growth do not cause each other is echoed by Shan *et al.* (2001), Shan and Morris (2002) and Nyasha and Odhiambo (2015).

Based on the literature reviewed in this study, it can be noted that due to the complexity and delicacy of the finance-growth causality subject, the empirical literature on the direction of causality between financial development – both bank- and market-based – and economic growth varies largely across countries and over time. It also varies depending on the empirical approach used and the proxies of bank-based and market-based financial development used. As such, a single study may support one view, or two views, or three, or all four views – depending on the proxies used or the countries covered in the study.

Despite being there four conflicting views, the popular view from the empirical literature front is in favour of the supply-leading response, where the development of the banking sector/stock markets is expected to precede the development of the real sector.

4. Estimation Technique and Empirical Analysis

4.1 Empirical Model Specifications

To address the shortfalls of bivariate Granger-causality, this study utilises a trivariate Granger-causality model within an autoregressive distributed lag (ARDL) bounds-testing framework, initially proposed by Pesaran and Shin (1999) and as later extended by Pesaran *et al.* (2001); to examine the causal relationship between bank-based financial development and economic growth, on the one hand; and the causal relationship between market-based financial development and economic growth, on the other hand.

The ARDL approach is the preferred technique because of the numerous advantages it has over other conventional estimation techniques (see also Duasa, 2007; Odhiambo, 2008; Majid, 2008; Pesaran and Shin, 1999). The ARDL procedure: i) Does not impose the restrictive assumption that all the variables under study must be integrated of the same order; ii) allows for inferences on long-run estimates, and it provides unbiased estimates of the long-run model and valid t-statistics – even when some of the regressors are endogenous; iii) takes a sufficient number of lags to capture the data-generating process in a general-to-specific modelling framework, in order to obtain optimal lag length per variable; iv) uses a single reduced-form equation; and v) has superior small sample properties. Therefore, the ARDL approach is considered most suitable for the analysis in this study.

The ARDL test for cointegration is conducted by taking in turn each variable as a dependent variable. The ARDL model used in this study can be expressed as follows (see also Odhiambo, 2010):

Model 1 - Bank-based financial development and economic growth

$$\Delta y_t = \alpha_0 + \sum_{i=1}^n \alpha_{1i} \Delta y_{t-i} + \sum_{i=0}^n \alpha_{2i} \Delta BFD_{t-i} + \sum_{i=0}^n \alpha_{3i} \Delta SAV_{t-i} + \alpha_4 y_{t-1} + \alpha_5 BFD_{t-1} + \alpha_6 SAV_{t-1} + \mu_{1t} \dots \dots \dots (1)$$

$$\Delta BFD_t = \beta_0 + \sum_{i=1}^n \beta_{1i} \Delta BFD_{t-i} + \sum_{i=0}^n \beta_{2i} \Delta y_{t-i} + \sum_{i=0}^n \beta_{3i} \Delta SAV_{t-i} + \beta_4 y_{t-1} + \beta_5 BFD_{t-1} + \beta_6 SAV_{t-1} + \mu_{2t} \dots \dots \dots (2)$$

$$\Delta SAV_t = \theta_0 + \sum_{i=1}^n \theta_{1i} \Delta SAV_{t-i} + \sum_{i=0}^n \theta_{2i} \Delta BFD_{t-i} + \sum_{i=0}^n \theta_{3i} \Delta y_{t-i} + \theta_4 y_{t-1} + \theta_5 BFD_{t-1} + \theta_6 SAV_{t-1} + \mu_{3t} \dots \dots \dots (3)$$

Model 2– Market-based financial development and economic growth

$$\Delta y_t = \delta_0 + \sum_{i=1}^n \delta_{1i} \Delta y_{t-i} + \sum_{i=0}^n \delta_{2i} \Delta MFD_{t-i} + \sum_{i=0}^n \delta_{3i} \Delta SAV_{t-i} + \delta_4 y_{t-1} + \delta_5 MFD_{t-1} + \delta_6 SAV_{t-1} + \varepsilon_{1t} \dots \dots \dots (4)$$

$$\Delta MFD_t = \gamma_0 + \sum_{i=1}^n \gamma_{1i} \Delta MFD_{t-i} + \sum_{i=0}^n \gamma_{2i} \Delta y_{t-i} + \sum_{i=0}^n \gamma_{3i} \Delta SAV_{t-i} + \gamma_4 y_{t-1} + \gamma_5 MFD_{t-1} + \gamma_6 SAV_{t-1} + \varepsilon_{2t} \dots \dots \dots (5)$$

$$\Delta SAV_t = \phi_0 + \sum_{i=1}^n \phi_{1i} \Delta SAV_{t-i} + \sum_{i=0}^n \phi_{2i} \Delta MFD_{t-i} + \sum_{i=0}^n \phi_{3i} \Delta y_{t-i} + \phi_4 y_{t-1} + \phi_5 MFD_{t-1} + \phi_6 SAV_{t-1} + \varepsilon_{3t} \dots \dots \dots (6)$$

Following Ang and McKibbin (2007), Narayan and Smyth (2008) and Odhiambo (2009a), trivariate causality models for this study, based on an error-correction mechanism, are expressed as follows:

Model 1 - Bank-based financial development and economic growth

$$\Delta y_t = a_0 + \sum_{i=1}^n a_{1i} \Delta y_{t-i} + \sum_{i=1}^n a_{2i} \Delta BFD_{t-i} + \sum_{i=1}^n a_{3i} \Delta SAV_{t-i} + \alpha_4 ECM_{t-1} + \mu_{1t} \dots \dots \dots (7)$$

$$\Delta BFD_t = \beta_0 + \sum_{i=1}^n \beta_{1i} \Delta y_{t-i} + \sum_{i=1}^n \beta_{2i} \Delta BFD_{t-i} + \sum_{i=1}^n \beta_{3i} \Delta SAV_{t-i} + \beta_4 ECM_{t-1} + \mu_{2t} \dots \dots \dots (8)$$

$$\Delta SAV_t = \theta_0 + \sum_{i=1}^n \theta_{1i} \Delta y_{t-i} + \sum_{i=1}^n \theta_{2i} \Delta BFD_{t-i} + \sum_{i=1}^n \theta_{3i} \Delta SAV_{t-i} + \theta_4 ECM_{t-1} + \mu_{3t} \dots \dots \dots (9)$$

Model 2 – Market-based financial development and economic growth

$$\Delta y_t = \delta_0 + \sum_{i=1}^n \delta_{1i} \Delta y_{t-i} + \sum_{i=1}^n \delta_{2i} \Delta MFD_{t-i} + \sum_{i=1}^n \delta_{3i} \Delta SAV_{t-i} + \delta_4 ECM_{t-1} + \varepsilon_{1t} \dots \dots \dots (10)$$

$$\Delta MFD_t = \gamma_0 + \sum_{i=1}^n \gamma_{1i} \Delta y_{t-i} + \sum_{i=1}^n \gamma_{2i} \Delta MFD_{t-i} + \sum_{i=1}^n \gamma_{3i} \Delta SAV_{t-i} + \gamma_4 ECM_{t-1} + \varepsilon_{2t} \dots \dots \dots (11)$$

$$\Delta SAV_t = \Phi_0 + \sum_{i=1}^n \Phi_{1i} \Delta y_{t-i} + \sum_{i=1}^n \Phi_{2i} \Delta MFD_{t-i} + \sum_{i=1}^n \Phi_{3i} \Delta SAV_{t-i} + \Phi_4 ECM_{t-1} + \varepsilon_{3t} \dots \dots \dots (12)$$

Where:

y = growth rate of real gross domestic product (a proxy for economic growth)

BFD = an index of bank-based financial development, which is a means-removed average of M2, M3 and credit provided to private sector by financial intermediaries, following the work of Demirguc-Kunt and Levine (1996) (a proxy for bank-based financial development)

MFD = an index of stock market development, which is a means-removed average of stock-market capitalisation, stock-market traded value and stock-market turnover, following the work of Demirguc-Kunt and Levine (1996) (a proxy for stock market development)

SAV = share of savings in GDP

ECM = Error correction term

$\alpha_0, \beta_0, \theta_0, \delta_0, \gamma_0$, and Φ_0 = respective constants; $\alpha_1 - \alpha_6, \beta_1 - \beta_6, \theta_1 - \theta_6, \delta_1 - \delta_6, \gamma_1 - \gamma_6$, and $\Phi_1 - \Phi_6$, = respective coefficients; Δ = difference operator; n = lag length; and μ_{it} and ε_{it} = white-noise error terms.

4.1 Sources of Data

This study utilises annual time-series data, covering the period 1980 to 2012. The primary data source for this study is the World Bank DataBank (World Bank, 2014). From this source, the following series from 1980 to 2012 for all the study countries were obtained: annual growth rate of real gross domestic product; ratio of M2 to GDP; ratio of M3 to GDP; credit provided to the private sector by financial intermediaries expressed as a percentage of GDP; and domestic savings as a percentage of GDP. From the same source, stock market capitalisation, total value of stocks traded and turnover ratio for all the study countries were obtained for the period 1987 to 2012. For all the study countries, data for the three later series for the period 1980 to 1986 were obtained from Emerging Stock Markets Factbook 1991, (International Finance Corporation, 1991) and from the study countries' stock exchange publications.

4.2 Unit Root Tests

Although the ARDL procedure does not require pre-testing the variable for unit root, the stationarity test provides guidance as to whether ARDL is suitable or not, since it is only appropriate for the analysis of variables that are integrated of order either zero [I(0)] or one [I(1)]. On this principle, before any analysis is done, the variables are first tested for stationarity, using the Phillips-Perron (PP) and the Perron (1997) (PPURoot) unit-root tests. The PPURoot is utilised to accommodate the possibility of structural breaks within the dataset. The results of the stationarity tests for all the variables for the developing countries are presented in Table 1 while those for the developed countries are presented in Table 2.

The results reported in Tables 1 and 2 show that the stationarity status of the variables varies depending on stationarity test performed. However, overall, all the variables were confirmed to be stationary after differencing them once; therefore, ARDL approach to the analysis of data is applicable. The next stage involves the performance of a co-integration test to examine whether the variables in each model are co-integrated.

4.3 Cointegration Analysis

It is of paramount importance to perform a bounds F-test for co-integration to ascertain the possible existence of any long-run relationship between the variables of interest before testing for causality. The ARDL-based cointegration test is performed in a two-step approach. Firstly, the order of lags of the first differenced variables in equations (1-6) is determined. This is followed by the application of a bounds F-test to equations (1-6), in order to establish the existence of a long-run relationship, if any, between the variables under study. The null hypothesis of no co-integration is tested against the alternative hypothesis of co-integration. The calculated F-statistic is compared with the critical values computed by Pesaran *et al.* (2001). If the calculated F-statistic lies above the upper bound level, the variables in question are co-integrated. However, if it lies below the lower-bound level, the variables are not co-integrated. If the calculated F-statistic falls within the upper and the lower bounds, the results are interpreted as inconclusive. Tables 3 and 4 report the results of the bounds F-test for co-integration for developing and the developed countries, respectively.

Table 3: Bounds F-test for Cointegration (Developing Countries)

South Africa

The results reported in Table 3 (Model 1) show that the cointegration relationship between bank-based financial development, savings and economic growth is sensitive to the choice of the dependent variable used. For South Africa, the variables are co-integrated only when economic growth (y) and savings ratio (SAV) are dependent variables. For Brazil, the variables are co-integrated only when economic growth (y) and bank-based financial development (BFD) are dependent variables. In Kenya, cointegration exists only when savings ratio (SAV) is the dependent variable. This is confirmed by the corresponding F-statistics in the respective functions which have been found to be statistically significant. As with the cointegration between bank-based financial development, savings and economic growth, the cointegration relationship between market-based financial development, savings and economic growth is also sensitive to the choice of the dependent variable used. As reported in Table 3 (Model 2), cointegration tends to exist in the savings function in Kenya, in the economic growth function in Brazil, and in the economic growth and savings functions in South Africa. These results have been confirmed by corresponding F-statistics in the respective functions, which are statistically significant.

The cointegration results for developed countries, as reported in Table 4, show that the cointegration relationship of the variables of interest is sensitive to the choice of the dependent variable used. However, the results indicate that cointegration between bank-based financial development, savings and economic growth has been accepted. This is confirmed by the F-statistics in economic growth and savings ratio functions of the three countries. The cointegration between market-based financial development, savings and economic growth has also been accepted, as confirmed by the F-statistics in the savings

function for the USA and both the economic growth and savings functions for the UK and Australia, which are statistically significant.

While the existence of cointegration between the variables suggests that there must be Granger-causality in at least one direction, it does not indicate the direction of causality between these variables (see Narayan and Smyth, 2004; Odhiambo, 2009a). According to Narayan and Smyth (2004) and Odhiambo (2009a), the short-run causal impact is determined by the F-statistics on the explanatory variables, whereas the long-run causal impact is measured through the error-correction term. Although the error-correction term has been incorporated in all the six equations of the Granger-causality model [equations (7) to (12)], it should, however, be noted that only equations where the null hypothesis of no co-integration is rejected, will be estimated with an error-correction term (Narayan and Smyth, 2004; Odhiambo, 2009a).

There are *a priori* four possibilities regarding the causal relationship between financial development (whether it is bank-based or market-based) and economic growth (Graff, 1999). The first being unidirectional causality from financial development to economic growth; the second being unidirectional causality from economic growth to financial development; the third being bidirectional causality between financial development and economic growth; and the fourth being no causality at all between the two.

4.4 Analysis of causality test based on error-correction model

Having found at least one cointegrating vector in both models for all the countries, the next step is to perform causality tests. This is done by incorporating the lagged error-correction

term into the relevant regression equations. The causality in this instance is examined through the significance of the coefficient of the lagged error-correction term and significance of the F-statistics of the explanatory variables as determined by the Wald Test or Variable Deletion Test. The results of the causality test within the Error-Correction Mechanism are reported in Table 5 and 6 for the developing and the developed countries, respectively.

The empirical results reported in Table 5 (Model 1) for bank-based financial development, savings and economic growth reveal that in South Africa and Kenya, there is no short-run or long-run Granger-causality between bank-based financial development and economic growth. This is confirmed by F-statistics of Δ BFD in the economic growth function and that of Δ y in the bank-based financial development function, which are both statistically insignificant. However, in Brazil there is bidirectional Granger-causality between bank-based financial development and economic growth. This applies in both the short and the long run. The short-run bidirectional causal flow is supported by the F-statistics of Δ BFD and Δ y in the corresponding functions, which are statistically significant. The long-run causal flow, on the other hand, is supported by the coefficients of the error-correction terms in the economic growth and the bank-based financial development functions, which are negative and statistically significant, as expected.

Other results reported in Model 1, for the developing countries, reveal that in South Africa: (i) there is distinct short-run and long-run unidirectional causality from savings to economic growth and (ii) there is distinct short-run and long-run unidirectional causality from bank-based financial development to savings. In Brazil (i) there is no causality between savings and economic growth and (ii) there is distinct short-run unidirectional causality from bank-based financial development to savings. In Kenya (i) there is no causality between savings and economic growth; (ii) there is long-run unidirectional causality from bank-based financial development to savings; and (iii) there is short-run bidirectional causality between bank-based financial development and savings.

The empirical results reported in Table 5 (Model 2) for market-based financial development, savings and economic growth, show that in South Africa and Brazil, there is

a distinct short-run unidirectional causal flow from economic growth to market-based financial development. This finding is confirmed by the F-statistics of Δy in the market-based financial development functions of the two countries, which are found to be statistically significant. The empirical results further reveal that in Kenya, there is short-run bidirectional causality between market-based financial development and economic growth.

Other results reported in Model 2 for the developing countries reveal that in South Africa there is: (i) short-run and long-run bidirectional causality between savings and economic growth; and (ii) short-run and long-run unidirectional causality from market-based financial development to savings. In Brazil there is: (i) distinct short-run and long-run unidirectional causality from savings to economic growth and (ii) short-run bidirectional causality between market-based financial development and savings. Finally, in Kenya there is: (i) short-run bidirectional causality between savings and economic growth; (ii) long-run unidirectional causality from economic growth to savings; and (iii) distinct short-run unidirectional causality from savings to market-based financial development.

From the developed countries front, the empirical results displayed in Table 6 (Model 1) reveal that for the USA, there is no Granger-causality between bank-based financial development and economic growth, irrespective of whether the causality is estimated in the short or long run. This is confirmed by the corresponding F-statistics in the economic growth and bank-based financial development functions, which are found to be statistically insignificant. For the UK, there is both short-run and long-run unidirectional causality from bank-based financial development to economic growth. This is confirmed by the F-statistic of ΔBFD in the economic growth function and the coefficient of the error-correction term

in the same function, which are both statistically significant. The empirical results further reveal the existence of short-run bidirectional causality between bank-based financial development and economic growth in Australia. However, for Australia, the results further reveal the presence of long-run unidirectional causality from bank-based financial development to economic growth.

Other results reported in Model 1 reveal that in the USA there is: (i) short-run and long-run bidirectional causality between savings and economic growth; (ii) short-run bidirectional causality between bank-based financial development and saving; and (iii) long-run unidirectional causality from bank-based financial development to savings. In the UK, however, there is: (i) distinct short-run and long-run unidirectional causality from economic growth to saving and (ii) no causality between bank-based financial development and savings. Finally, in Australia there is: (i) no causality between savings and economic growth and (ii) distinct short-run and long-run unidirectional causality from bank-based financial development to savings.

The empirical results reported in Table 6 (Model 2) for the developed countries show that there is no Granger-causality between market-based financial development and economic growth in the UK and Australia. However, there is distinct short-run unidirectional causality from market-based financial development to economic growth in the USA.

Other results reported in Model 2 reveal that in the USA there is: (i) short-run bidirectional causality between savings and economic growth; (ii) long-run unidirectional causality from economic growth to savings and (iii) distinct short-run unidirectional causality from

savings to market-based financial development. In the UK there is: (i) distinct short-run and long-run unidirectional causality from savings to economic growth; (ii) short-run bidirectional causality between market-based financial development and savings; and (iii) long-run unidirectional causality from market-based financial development to savings. Finally, in Australia there is distinct: (i) short-run and long-run unidirectional causality from savings to economic growth; and (ii) short-run and long-run unidirectional causality from market-based financial development to savings.

Overall, the empirical results reported in Tables 5 and 6, for all the (Models 1 and 2) imply that: (i) in South Africa, it is the real sector that drives stock market development; (ii) in Brazil, banking sector development and the real sector drive each other, but it is the real sector that propels stock market development; (iii) in Kenya, the stock market and the real sector drive each other; (iv) in the USA, it is the stock market that drives the real sector; (v) in the UK, it is the banking sector that drives the real sector; and (vi) in Australia, the banking sector and the real sector drive each other in the short run but it is the banking sector that propels the real sector in the long run. A summary of these results are presented in Table 7.

Table 7: Summary of Models 1 and 2 Results (All Study Countries)

	Model 1 (BFD & y)		Model 2 (MFD & y)	
	Direction of Causality		Direction of Causality	
	Short Run	Long Run	Short Run	Long Run
Developing Countries				
South Africa	No causality	No causality	y → MFD	No causality
Brazil	BFD ↔ y	BFD ↔ y	y → MFD	No causality
Kenya	No causality	No causality	MFD ↔ y	No causality
Developed Countries				
USA	No causality	No causality	MFD → y	No causality
UK	BFD → y	BFD → y	No causality	No causality
Australia	BFD ↔ y	BFD → y	No causality	No causality

Notes: y=economic growth; BFD=bank-based financial development; MFD=market-based financial development; and → indicates direction of causality

As summarised in Table 7 (Model 1) bank-based financial development Granger-causes economic growth in one country, the UK; bank-based financial development and economic growth Granger-cause each other in one country, Brazil, while bank-based financial development and economic growth are not causally related in three countries, South Africa, Kenya and the USA. The results of Model 2 show that market-based financial development Granger-causes economic growth in one country, the USA while economic growth Granger-causes market-based financial development in two countries, South Africa and Brazil. Model 2 results also indicate that market-based financial development and economic growth Granger-cause each other in one country, Kenya but they are not causally related in two countries, Australia and the UK.

Although the results of this study are not uniform across the study countries, they are consistent with results of similar earlier work. From the bank-based financial development

and economic growth causality angle, the results reveal evidence in support of finance-led growth in the short and long-run in the case of the UK but only in the long run in the case of Australia (see also Christopoulos and Tsionas, 2004; Majid, 2008; Odhiambo, 2009a). Evidence supporting bidirectional causality was found in both the short run and the long run in Brazil – and only in the short run in Australia (see, among others, Sinha and Macri, 2001; Shan and Jianhong, 2006; Abu-Bader and Abu-Qarn, 2008). However, a neutrality view was supported in the cases of South Africa, Kenya and the USA. These results are consistent with those obtained by Shan *et al.* (2001) and Shan and Morris (2002), among others. From the market-based financial development and economic growth causality front, the results largely support the neutrality view in the long run in all the countries, as also in the short-run for Australia and the UK. The growth-led finance view is supported in the short run for South Africa and Brazil (see also Athanasios and Antonios, 2012; Shan and Morris, 2002), while the finance-led growth hypothesis is supported in the USA, in the short run. Evidence consistent with the bidirectional view is found only in Kenya, in the short run (see Cheng, 2012; Marques *et al.*, 2013).

From the policy implication front, in the UK, where bank-based financial sector development leads economic growth, policy makers are recommended to consider banking sector enhancing policies in order to stimulate the real sector. However, Brazil and Australia are likely to benefit from both growth-enhancing and banking sector-enhancing policies since the real sector and the banking sector drive each other. In the USA, where market-based financial sector development drives growth of the real sector, pro-market-based financial sector development policies are recommended in order to further stimulate the real sector. In South Africa and Brazil, where it is the real sector that stimulates the development of the market-based financial sector, the study recommends policies that

promote the development of the real sector of the economy to be put in place to further stimulate the financial markets. However, in Kenya policy makers are recommended to draft balanced policies that favour stock market development on the one hand and economic growth on the other.

The regression of the underlying causality model passes all the diagnostic tests against serial correlation, functional form, normality and heteroscedasticity.

5. Conclusion

In this study, the causal relationship between bank-based financial development and economic growth; and the relationship between market-based financial development and economic growth in three developing countries – South Africa, Brazil and Kenya – and three developed countries – the United States of America, the United Kingdom and Australia – is examined for the period from 1980 to 2012. To address the omission of variable bias, the study uses savings as an intermittent variable – thereby creating a trivariate Granger-causality model. The study employs the method of means-removed average to construct both bank- and market-based financial development indices. Using the newly developed ARDL bounds testing approach to co-integration, and the ECM-based Granger-causality model, the results were found to vary from country to country, and over time. The results also tend to vary, depending on the proxy used to measure the level of financial development. Overall, the study finds that there is a long-run causal flow from bank-based financial development to economic growth in the UK and in Australia; a distinct feedback loop in the case of Brazil; and a neutrality relationship in the case of Kenya, South Africa and the USA. For market-based financial development, the study finds evidence of bidirectional causality in the case of Kenya; a demand-following hypothesis in South Africa and Brazil; and a neutrality relationship in the case of Australia and the UK. The study, therefore, repudiates the traditional argument, which contends that the finance-growth nexus follows a supply-leading phenomenon.
