## CHAPTER 5

## RESULTS OF THE INVESTIGATION

### 5.1 INTRODUCTION

The data gathered from the empirical investigation was carefully scrutinised for obvious flaws like omission of items, specific patterns of answering and marking more than one score per item. Attention was also paid to written comments by adolescents. Hereafter the following steps were conducted to analyse and interpret the results:

- An item analysis of all the items for each of the six dimensions and for the total self-evaluation score
- Determining the reliability of the instrument
- Determining the validity of the instrument
- Determining the norms of the instrument
- Testing of the hypothesis

### 5.2 ITEM ANALYSIS OF THE SELF-EVALUATION QUESTIONNAIRE (SEQ)

The self-evaluation questionnaire consists of six sections, namely the physical self, social self, academic self, family self, value self and psychology self. An item analysis was done for each section (ten items each) as well as for the whole questionnaire ( 60 items in all) in order to establish what the contribution each of the items made to its particular section, and to the total score of the questionnaire.

The first aspect to be taken into consideration when doing an item analysis, is whether the item-total correlation is low or negative. If it is, it means that an item has been omitted.

The second aspect to be taken into consideration is the Alpha-reliability coefficient. The reliability coefficient was calculated for each of the sections of the questionnaire as well as for the total
questionnaire, in the event that all items are retained. The reliability coefficient is also calculated should specific items be omitted. An item will only be omitted if it results in a significant increase in the reliability of that particular section.

Based on the item-total correlation and the reliability coefficient, it is then decided whether a specific item must be retained or be omitted. The following tables, namely table 5.1, 5.2, 5.3, 5.4, 5.5, 5.6 and 5.7, indicate that all items have showed a positive correlation with the total. They also indicate that the reliability coefficient of the particular section and of the total questionnaire is not significantly higher if any item has been left out. Therefore all items of the particular sections have been retained.

### 5.3 RELIABILITY OF THE INSTRUMENT

According to Mulder (1989:209), no standardised test is complete unless there is an indication of its reliability. Schumacher \& McMillan (1993:227) define reliability as referring to the consistency of measurement; the extent to which results are similar across different forms of the same instrument or occasions of data collecting. This is done to reduce the influence of chance or other variables unrelated to the purpose of the measure. Guy, Edgley, Arafat and Allen (1987:169) declare that a measuring device is reliable if it produces the same object, assuming the object itself is stable. Reliability therefore refers to repeatability of a testee's score in the same test on different occasions, or in different tests with equivalent items, or under different examination conditions. In other words, the concept of reliability has to do with error of measurement which leads to fluctuations in the testee's score. A test must be consistent in what it measures, given standard conditions of measurement. As with any measuring instrument, an inconsistent test is not likely to be of much use.

The reliability coefficient is a correlation statistic comparing two sets of scores obtained by the same individual. The scale is from zero $(0,00)$ to one $(1,00)$. If the coefficient is high, the instrument has little error and is highly reliable. An acceptable range of reliability coefficient for most instruments is between 0,70 and 0,90 (Schumacher \& McMillan 1993:227). The closer the reliability of a measuring instrument is to one (1), the smaller the difference is between the variance of the actual score and the observed score. Therefore, when an instrument is developed, an attempt is made to obtain a reliability coefficient as close to one as possible.

Concerning the instrument being used in this research, reliability was arrived at by calculating the alpha coefficient for each of the six sections as well as for the total questionnaire ( 60 items). As shown by table 5.8 below, the reliability coefficient for the whole questionnaire is 0,932 . This value is very close to one (1) and therefore the questionnaire can be considered to be a reliable measuring instrument.

TABLE 5.8: RELIABILITY OF THE SELF-EVALUATION QUESTIONNAIRE (SEQ)

| DIMENSION | ALPHA-RELIABILITY <br> COEFFICIENT | NUMBER OF ITEMS |
| :--- | :---: | :---: |
| PHYSICAL | 0,754 | 10 |
| SOCIAL | 0,674 | 10 |
| ACADEMIC | 0,724 | 10 |
| FAMILY | 0,840 | 10 |
| VALUE | 0,702 | 10 |
| PSYCHOLOGICAL | 0,729 | 10 |
| SEQ IN TOTALITY | 0,932 | 60 |

### 5.4 VALIDITY OF THE INSTRUMENT

Validity refers to whether the items in a test do in fact test what they are supposed to test (Wiersma 1991:170; Pienaar 1998:277). Validity answers the question as to whether the instrument measures the characteristics, traits or whatever for which it has been designed. Mathe (1997:158) contends that a test is not valid per se but is only valid for a particular purpose and for a particular group. A measure is said to be valid if the true quantity and the measured quantity are one and the same. As in the case of reliability, no standardised measuring instrument is complete unless an explicit statement is made about its validity. Rambiyana (2000:86) suggests that a test can be reliable but not valid. This means that it can measure something consistently but will still not measure what it is intended to measure. He states that a measure cannot be valid unless it is reliable.

### 5.4.1 Construct validity

It often happens that a questionnaire consists of different subsections, measuring different constructs. The questionnaire used in this study is an example of such a situation since it measures physical self, social self, academic self, family self, value self and psychological self with regard to self-evaluation.

Although the test consists of different constructs, these constructs are related to one another and to the total construct of the test because they all deal with the self. One would therefore expect to find a significant positive correlation among the constructs (sections) and between each construct (section) and the construct measured by the questionnaire in total (self-evaluation). If such correlations exist, one can regard the questionnaire to be construct-valid. In order to determine construct validity, correlation coefficients were calculated between the six different constructs and between each construct and the total of the test. These correlation coefficients appear in table 5.9 below.

TABLE 5.9: CONSTRUCT VALIDITY

|  | CTOTAL | CPHYS | CSOC | CACAD | CFAM | CVAL | CPSY |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |  |  |  |
| CTOTAL |  | 0,83 | 0,82 | 0,82 | 0,77 | 0,77 | 0,85 |
| CPHYS |  |  | 0,59 | 0,57 | 0,63 | 0,56 | 0,65 |
| CSOC |  |  |  | 0,65 | 0,54 | 0,58 | 0,63 |
| CACAD |  |  |  |  | 0,49 | 0,58 | 0,72 |
| CFAM |  |  |  |  |  | 0,54 | 0,59 |
| CVAL |  |  |  |  |  |  | 0,53 |
| CPSY |  |  |  |  |  |  |  |

$\mathrm{p}<0,01$ for all correlation coefficients.

All correlations seem to be highly positive correlations, significant on the 1 percent level. The different constructs therefore strongly relate to one another as expected and consequently the test may be considered construct-valid.

### 5.5 DETERMINING THE NORMS OF THE INSTRUMENT

A norm is an objective standard whereby the scores which a testee receives on a measuring instrument are interpreted (Pienaar 1998:79).

Stanines (standard scores divided into nine categories as in table 5.10) have been used to determine the norms. Norms are provided for the test so that a researcher administering the test to a group of testees at a later stage will be in a position to interpret the score obtained by each testee in terms of the results obtained by the standardisation group. The term "stanine" is an amalgamation of the two words "standard" and "nine", and it signifies that standard scores have been grouped into nine categories (Mulder 1989:201). To calculate the stanines for each of the dimensions of the SEQ, as well as for the total SEQ, the cumulative percentages for each of the sections and the total SEQ were obtained. The stanines obtained are set out in tables 5.10 to 5.17 below.

TABLE 5.10: LIMITS AND AREAS OF STANINES

| STANINES | LIMITS |  |  | \% OF AREA |
| :---: | :---: | :---: | :---: | :---: |
| 9 | +t | to | $+1,75 \mathrm{z}$ | 4 |
| 8 | +t 1,75z | to | +1,25z | 7 |
| 7 | +t 1,25z | to | $+0,75 z$ | 12 |
| 6 | +t 0,75z | to | $+0,25 z$ | 17 |
| 5 | +t 0,25z | to | -0,25z | 20 |
| 4 | +t 0,25z | to | -0,75z | 17 |
| 3 | +t 0,75 | to | -1,25z | 12 |
| 2 | +t 1,25z | to | $-1,75 z$ | 7 |
| 1 | +t 1,75z | to |  | 4 |

| 285 | 2 | 37,6 |  |
| 287 | 1 | 38,8 |  |
| 289 | 3 | 39,9 |  |

| 290 | 4 | 41,4 |  |
| :--- | :--- | :--- | :--- |
| 291 | 4 | 43,0 |  |
| 292 | 2 | 43,7 |  |
| 293 | 7 | 46,4 |  |
| 294 | 5 | 48,3 |  |
| 295 | 3 | 5,4 | 5 |
| 296 | 2 | 50,2 |  |
| 297 | 3 | 52,1 |  |
| 298 | 2 | 53,6 |  |
| 299 | 4 | 54,4 |  |
| 300 | 2 | 56,3 |  |
| 301 | 5 | 58,2 |  |
| 302 | 5 | 58,6 |  |
| 303 | 1 | 59,3 |  |
| 304 | 2 | 60,8 |  |
| 305 | 4 | 63,9 |  |
| 306 | 8 | 66,5 |  |
| 307 | 4 | 68,1 |  |
| 308 | 3 | 69,6 |  |
| 309 | 4 | 71,5 |  |
| 310 | 4 | 74,0 |  |
| 311 | 5 | 75,7 |  |
| 312 | 4 | 77,6 |  |
| 313 | 4 |  |  |
| 314 | 3 | 5 |  |

| 317 | 2 | 78,3 |  |
| :--- | :--- | :--- | :--- |
| 318 | 1 | 78,7 |  |
| 319 | 5 | 80,6 |  |
| 320 | 4 | 82,1 |  |
| 321 | 4 | 83,7 |  |
| 322 | 1 | 84,0 | 7 |
| 323 | 2 | 84,8 |  |
| 324 | 2 | 85,6 |  |
| 325 | 4 | 87,8 |  |
| 326 | 2 | 88,6 |  |
| 327 | 2 |  |  |

| 328 | 3 | 89,7 |  |
| :---: | :---: | :---: | :---: |
| 329 | 1 | 90,1 |  |
| 330 | 1 | 90,5 |  |
| 331 | 3 | 91,6 | 8 |
| 334 | 1 | 92,0 |  |
| 335 | 5 | 93,9 |  |
| 336 | 2 | 95,7 |  |
| 337 | 2 | 95,8 |  |
| 338 | 1 | 97,0 |  |
| 339 | 3 | 98,1 |  |
| 340 | 3 | 98,5 | 9 |
| 349 | 1 | 98,9 |  |
| 353 | 1 | 99,2 |  |
| 360 | 1 | 100,0 |  |

By dividing the categories up as in table 5.10 and then applying them to the six dimensions of the SEQ as well as to the total SEQ, it is possible to establish whether an individual's self-evaluation is below average or above average. As a general rule it is understood that the bottom three stanines ( 1,2 and 3 ) as average and the top three stanines ( 7,8 and 9 ) as above average (Mulder 1989:205). The classification of the scores is given in table 5.18 below.

TABLE 5.18: CLASSIFICATION OF THE SELF-EVALUATION (SELF-CONCEPT) SCORES INTO CATEGORIES

| DIMENSION | BELOW <br> AVERAGE | AVERAGE | ABOVE <br> AVERAGE |
| :--- | :---: | :---: | :---: |
| Physical self | $10-41$ | $42-55$ | $56-60$ |

| Social self | $10-40$ | $41-50$ | $51-60$ |
| :--- | :---: | :---: | :---: |
| Academic self | $10-40$ | $41-51$ | $52-60$ |
| Family self | $10-33$ | $34-40$ | $41-60$ |
| Value self | $10-43$ | $44-53$ | $54-60$ |
| Psychological self | $10-40$ | $41-51$ | $52-60$ |
| Total Questionnaire | $60-265$ | $266-315$ | $317-360$ |

### 5.6 TESTING OF THE HYPOTHESIS

### 5.6.1 The physical self

With regard to the hypothesis as stated in chapter 1 , the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the physical self.

The following abbreviations are used in table 5.19 below.

PPHYS-Average scores given by parents evaluating the physical self of their adolescents.
TPHYS-Average scores given by teachers evaluating the physical self of their adolescents.
CPHYS-Average scores given by adolescents evaluating their physical self.

The average scores given by each of the three groups with regard to the physical self are shown in table 5.19 below.

TABLE 5.19: PHYSICAL SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | N | Mean | Std. Dev. |
| :---: | :--- | :---: | :---: |
| CPHYS | 124 | 48,30 | 8,15 |
| PPHYS | 124 | 42,09 | 7,27 |
| TPHYS | 124 | 43,05 | 8,82 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.20 below.

TABLE 5.20: THE PHYSICAL SELF-DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, TEACHERADOLESCENT AND PARENT-ADOLESCENT

| Evaluation of the <br> adolescent's <br> physical self | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :--- | :---: | :---: | :---: | :---: | :--- |
| Teacher-parent | 124 | 0,95 | 7,56 | 1,41 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 5,25 | 12,94 | 4,52 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 6,21 | 12,14 | 5,69 | $\mathrm{p}<0,01$ |

According to the results in table 5.20 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. This means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same adolescent, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent-adolescent is significantly higher than the difference between the means of parents-teachers. This means that the adolescents evaluated their physical self as significantly higher than
what their teachers and parents did. In other words, the adolescents' opinions of their physical abilities and appearances , are significantly higher than the opinions of parents and teachers concerning the same abilities, appearances, and so on.

Where teachers and parents evaluated the same adolescents on a physical level, no significant difference was obtained. This means that teachers and parents are more in agreement concerning the physical self of a specific adolescent. For example, if an adolescent thinks he or she is more attractive than their peers, the parents and teachers of this adolescent will not necessarily agree and will probably regard this adolescent as not more attractive than his or her peers.

### 5.6.2 The social self

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the social self.

The following abbreviations are used in table 5.21 below.

PSOC-Average scores given by parents evaluating the social self of their adolescents.
TSOC-Average scores given by teachers evaluating the social self of their adolescents.
CSOC-Average scores given by adolescents evaluating their social self.

The average scores given by each of the three groups with regard to the social self are shown in table 5.21 below.

TABLE 5.21: SOCIAL SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CSOC | 124 | 43,48 | 7,23 |
| PSOC | 124 | 40,87 | 6,52 |
| TSOC | 124 | 39,72 | 8,15 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.22 below.

TABLE 5.22: SOCIAL SELF: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, ADOLESCENT-CHILD AND PARENT-ADOESCENT

| Evaluation of the <br> adolescent's social <br> self | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Teacher-parent | 124 | 1,15 | 7,47 | 1,71 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 3,76 | 11,24 | 3,72 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 2,61 | 10,31 | 2,82 | $\mathrm{p}<0,01$ |

According to the results in table 5.22 the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. It means that where the teacher-adolescent and the parentadolescent scores are compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same adolescents, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent-adolescent is significantly higher than the difference between the means of parents-teachers. This means that the adolescents evaluated their social self as significantly higher than what their teachers and parents did. In other words, the adolescents' opinions of their social relationships and relationships with friends, are significantly higher than the opinions of parents and teachers concerning the same social relationships, relationship with friends, and so on.

Where teachers and parents evaluated the same adolescents on a social level, no significant difference was obtained. This means that parents and teachers are more in agreement concerning the social self of a specific adolescent. For example, if an adolescent thinks he or she will be the first to be chosen in a team, the parents and teachers of this adolescent will not necessarily agree.

### 5.6.3 The academic self

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the academic self.

The following abbreviations are used in table 5.23 below:

PACAD-Average scores given by parents evaluating the academic self of their adolescents.
TACAD-Average scores given by teachers evaluating the academic self of their adolescents.
CACAD-Average scores given by adolescents evaluating their academic self.

The average scores given by each of the three groups with regard to the academic self are shown in table 5.23 below.

TABLE 5.23: ACADEMIC SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CACAD | 124 | 43,48 | 8,13 |
| PACAD | 124 | 40,59 | 7,19 |
| TACAD | 124 | 41,10 | 9,07 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.24 below.

TABLE 5.24: THE ACADEMIC SELF: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, TEACHER-ADOLESCENT AND PARENT-ADOLESCENT

| Evaluation of the <br> adolescent's <br> academic self | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Teacher-parent | 124 | 0,52 | 7,39 | 0,78 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 2,74 | 13,08 | 2,33 | $\mathrm{p}<0,05$ |
| Parent-adolescent | 124 | 3,26 | 11,24 | 3,22 | $\mathrm{p}<0,01$ |

According to the results in table 5.24 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-learner scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. This means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With
regard to the scores given by teachers-parents to the same adolescents, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teachers-adolescents and parents-adolescents is significantly higher than the difference between the means of parents-teachers. This means that the adolescents evaluated their academic self as significantly higher than what their teachers and parents did. In other words, the adolescents' opinions of their academic abilities, faster understanding of school subjects than peers and reading faster, are significantly higher than the opinions of parents and teachers concerning the same academic abilities, understanding of school subjects, reading faster, and so on.

Where teachers and parents evaluated the same adolescents on an academic level, no significant difference was obtained. This means that parents and teachers are more in agreement concerning the academic self of a specific adolescent. For example, if an adolescent thinks that he or she is a fast reader, the parents and teachers of this adolescent will not necessarily agree and will probably regard this adolescent as an average or even poor reader.

### 5.6.4 The family self

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the family self.

The following abbreviations are used in table 5.25 below:

PFAM-Average scores given by parents evaluating the family self of their adolescents.
TFAM-Average scores given by teachers evaluating the family self of their adolescents.
CFAM-Average scores given by adolescents evaluating their family self.

The average scores given by each of the three groups with regard to the family self are shown in table 5.25 below.

TABLE 5.25: FAMILY SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CFAM | 124 | 35,09 | 5,77 |
| PFAM | 124 | 29,92 | 5,74 |
| TFAM | 124 | 29,68 | 7,33 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.26 below.

TABLE 5.26: FAMILY SELF: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, TEACHER-ADOLESCENTS AND PARENT-ADOLESCENTS

| Evaluation of the <br> adolescent's family <br> self | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
| Teacher-parent | 124 | 0,23 | 6,29 | 0,41 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 5,41 | 9,43 | 6,39 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 5,18 | 8,40 | 6,86 | $\mathrm{p}<0,01$ |

According to the results in table 5.26 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. It means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same children, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent- adolescent is significantly higher than the difference between the means of parents-teachers. This means that the adolescent evaluated their family self as significantly higher than what their teachers and parents did. In other words, the adolescents' opinions of their good relationship with family members and being on good terms with family members, are significantly higher than the opinions of parents and teachers concerning the same relationships with family members, being on good terms with family members, and so on.

Where teachers and parents evaluated the same adolescents regarding relationship with family members, no significant difference was obtained. This means that teachers and parents are more in agreement concerning the relationships with family members of a specific adolescent. For example, if an adolescent thinks that he/she is on good terms with his/her family members, the parents and teachers of this adolescent will not necessarily agree and will probably regard this adolescent as being not on good terms with his/her family members.

### 5.6.5 The value self

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the value self.

The following abbreviations are used in table 5.27 below:

PVAL-Average scores given by parents evaluating the value self of their adolescents.
TVAL-Average scores given by teachers evaluating the value self of their adolescents.
CVAL-Average scores given by adolescents evaluating their value self.

The average scores given by each of the three groups with regard to the value self are shown in table 5.27 below.

TABLE 5.27: VALUE SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CVAL | 124 | 46,26 | 6,97 |
| PVAL | 124 | 41,44 | 6,53 |
| TVAL | 124 | 40,64 | 8,33 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.28 below.

TABLE 5.28: THE VALUE SELF: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION, AND t-TESTS FOR TEACHER-PARENT, TEACHER-ADOLESCENT AND PARENT-ADOLESCENT

| Evaluation of the <br> adolescent's value <br> self | N | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :---: | :---: | :---: | :---: | :---: | :---: |

| Teacher-parent | 124 | 0,81 | 7,78 | 1,15 | $\mathrm{p}>0,05$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Teacher-adolescent | 124 | 5,62 | 11,66 | 5,37 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 4,81 | 10,16 | 5,28 | $\mathrm{p}<0,01$ |

According to the results in table 5.28 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. This means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same adolescent, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent-adolescent is significantly higher than the difference between the means of parents-teachers. This means that the adolescents evaluated their value self as significantly higher than what their teachers and parents did. In other words, the adolescents' opinions of their value self, their honesty and their truthfulness, are significantly higher than the opinions of parents and teachers concerning the same value self, their honesty and their truthfulness .

Where teachers and parents evaluated the same adolescents regarding value self, no significant difference was obtained. This means that teachers and parents are more in agreement concerning the value self of a specific adolescent. For example, if an adolescent thinks that he/she is a good person, better than his/her peers, the parents and teachers of this adolescent will not necessarily agree and will probably regard this adolescent as not better than his/her peers.

### 5.6.6 The psychological self

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation score of the adolescent and the self-evaluation scores given by parents and teachers with regard to the psychological self.

The following abbreviations are used in table 5.29 below:

PPSY-Average scores given by parents evaluating the psychological self of their adolescents. TPSY-Average scores given by teachers evaluating the psychological self of their adolescents. CPSY-Average scores given by adolescents evaluating their psychological self.

The average scores given by each of the three groups with regard to the psychological self are shown in table 5.29 below.

TABLE 5.29: PSYCHOLOGICAL SELF: AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CPSY | 124 | 43,78 | 7,63 |
| PPSY | 124 | 40,81 | 7,39 |
| TPSY | 124 | 40,25 | 8,38 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance. The results appear in table 5.30 below.

TABLE 5.30: THE PSYCHOLOGICAL SELF: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, TEACHER-ADOLESCENT AND PARENT-ADOLESCENT

| Evaluation of the <br> adolescent's <br> psychological self | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T/ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Teacher-parent | 124 | 0,56 | 7,64 | 0,81 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 3,53 | 11,98 | 3,28 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 2,98 | 11,60 | 2,86 | $\mathrm{p}<0,01$ |

According to the results in table 5.30 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. This means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same adolescents, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent-adolescent is significantly higher than the difference between the means of parents-teachers. This means that the adolescents evaluated their psychological self as significantly higher than what their teachers and parents did. In other words, the adolescents' opinions of their leadership abilities, their being successful in life and their quick decision-making abilities, are significantly higher than the opinions of parents and teachers concerning the same leadership abilities, their being successful in life and their quick decision-making abilities.

Where teachers and parents evaluated the same adolescents regarding psychological self, no significant difference was obtained. This means that teachers and parents are more in agreement concerning the psychological self of a specific adolescent. For example, if an adolescent thinks he/she is good at decision-making, the parents and teachers of this adolescent will not necessarily agree and will probably regard this adolescent as not better than his/her peers on the aspect of decision-making.

### 5.6.7 The total self-evaluation questionnaire (SEQ)

With regard to the hypothesis as stated in chapter 4, the following null hypothesis was tested:

There will be no significant difference between the self-evaluation scores of the adolescents and the self-evaluation scores given by parents and teachers with regard to the whole/total self-evaluation questionnaire.

The following abbreviations are used in table 5.31 below:

PTOTAL-Average scores given by parents with regard to the self-evaluation of their adolescents. TTOTAL-Average scores given by teachers with regard to the self-evaluation of their adolescents. CTOTAL-Average scores given by adolescents evaluating their self.

The average scores given by each of the three groups with regard to self-evaluation are shown in table 5.31 below.

TABLE 5.31: THE TOTAL QUESTIONNAIRE (SEQ): AVERAGE SCORES GIVEN BY ADOLESCENTS, PARENTS AND TEACHERS

| Variable | $\mathbf{N}$ | Mean | Std. Dev. |
| :---: | :---: | :---: | :---: |
| CTOTAL | 124 | 275,81 | 38,06 |
| PTOTAL | 124 | 248,94 | 37,92 |
| TTOTAL | 124 | 248,94 | 45,29 |

To determine whether the averages differ significantly, at-test for dependent variables was used in each instance .The results appear in table 5.32 below.

TABLE 5.32: THE TOTAL QUESTIONNAIRE: DIFFERENCES BETWEEN THE MEANS, STANDARD DEVIATION AND t-TESTS FOR TEACHER-PARENT, TEACHER-ADOLESCENT AND PARENT-ADOLESCENT

| Evaluation of the <br> adolescent's self- <br> evaluation | $\mathbf{N}$ | Difference between <br> means | Std. <br> Dev. | T-value | Prob>/T// |
| :--- | :---: | :---: | :---: | :---: | :--- |
| Teacher-parent | 124 | 0,88 | 38,11 | 0,26 | $\mathrm{p}>0,05$ |
| Teacher-adolescent | 124 | 27,75 | 63,67 | 4,85 | $\mathrm{p}<0,01$ |
| Parent-adolescent | 124 | 26,87 | 58,57 | 5,11 | $\mathrm{p}<0,01$ |

According to the results in table 5.32 above, the null hypothesis can be rejected with regard to teacheradolescent scores and with regard to parent-adolescent scores. With regard to teacher-parent scores, the null hypothesis cannot be rejected. It means that where the teacher-adolescent and the parentadolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers-parents to the same adolescents, however, no significant difference in their average scores could be obtained.

In both instances where the null hypothesis is rejected, the difference between the means of the teacheradolescent and parent-adolescent is significantly higher than the difference between the means of parents-teachers.

Where teachers and parents evaluated the same adolescent, no significant difference was obtained, which means that parents and teachers see eye to eye or are more in agreement concerning the total evaluation of adolescents. The adolescents' opinions about themselves are not the same as the opinions of parents and teachers about the same adolescents. The adolescents' opinions about themselves are significantly higher than the opinions of parents and teachers concerning the same adolescents.

### 5.7 CONCLUSION.

In all instances stated above, the null hypothesis can be rejected with regard to teacher -adolescent scores and with regard to parent-adolescent scores. Except in one instance where the null hypothesis can be rejected at the 5 percent level of significance, in all other instances the null hypothesis can be rejected at the 1 percent level of significance.

Concerning the teacher-parent scores, the null hypothesis cannot be rejected. This has been the case with regard to all dimensions and with regard to the total questionnaire. In all instances where the teacher-adolescent and parent-adolescent scores were compared, a significant difference between their averages was obtained. With regard to the scores given by teachers and parents to the same adolescents, no significant difference in their average scores could be obtained, either for the different dimensions or for the total questionnaire.

In all instances where the null hypothesis was rejected, the mean of adolescent was significantly higher than that of teachers and that of parents. The means of parents and teachers were almost the same for family self, psychological self and the total questionnaire. We can therefore state that the adolescents rated themselves high, higher than the teachers and parents did and we can therefore assume that they (the adolescents) were subjective in their self-valuation.
