REVIEW PROCESS

The first call for papers went out early in December 2021, with a due date of abstract submissions by 1 March 2022. A total of 219 abstracts were submitted and abstract acceptance was communicated by 18 March. The abstracts were blind peer-reviewed by appointed subject chairs who are experts within their respective fields. Authors with accepted abstracts were invited to submit a full paper with a deadline of 29 April 2022. A total of 143 full papers were received, of which one was not accepted because of a high similarity index. The remaining 142 papers were subjected to a double-blind peer review process managed by the head of reviewers according to South Africa's Department of Higher Education and Training (DHET) refereeing standards. Subject chairs within the different tracks of Business Management, Economics, Finance, Public Relations and Human Resource Management, Marketing, Sport and Leisure and Technology Integration identified reviewers unknown to the authors and from a different institution for the review process. Likewise, the identity and the institution of the reviewer remained anonymous.

A database of possible reviewers was compiled by the SSIRC organising committee, indicating each reviewer's area of expertise. Each subject chair drew from this database within their subject field or included new additions to the list of reviewers. Some of the reviewers were authors of papers, however, several reviewers were from international institutions. The list of the scientific committee and reviewers is provided within the proceedings. At least two anonymous reviewers reviewed each paper submission and where discrepancies occurred, a third reviewer was used, or the head of the reviewers performed the third review. Papers were reviewed according to the following criteria:

- Significance of the paper
- Originality
- Content including the abstract, quality literature review and/or research question
- Appropriateness of research methodology
- Adequacy of results and discussion
- Technical; including language, spelling and references.

Authors received a reviewer report on the above-mentioned aspects and attended to comments and recommendations where needed by submitting a change log when required by reviewers. Four papers were rejected after review. The second manuscript submissions, if needed, were assessed by the head of reviewers when papers were returned, or alternatively reviewed for a second round by the reviewer according to their comments. In total, 113 full papers were included in the conference proceeding.

PREFACE

The Social Sciences International Research Conference (SSIRC) 2022 proceedings contain full papers submitted to the hybrid Social Sciences International Research Conference held in-person and virtually from 19 to 21 October 2022. The conference was organised and hosted by the Faculty of Economic and Management Sciences of the North-West University, South Africa, in partnership with the Open University of Mauritius.

SSIRC 2022 provided high-quality pre-conference workshops, addressing the need for expanded research methodologies using new technologies. The PhD round table discussion session also provided a novel opportunity to develop young social science researchers as they engaged with experienced faculty. The conference keynote address by the Honourable Mr Deepak Balgobin, the Mauritian Minister of Information and Technology, Communication and Innovation on Artificial intelligence and the keynote from Nepal, Prof Biju Thapalia address on “The future of Supply Chain: response to disruption, challenges and opportunities”, denoted the conference theme excellently. Partnering with the Open University of Mauritius has equally brought new opportunities for conference delegates, and we thank the Local Organising Committee members from OU for their contribution to the conference’s success.

The conference solicited and attracted research submissions on all aspects of the Social Sciences. A total of 143 full papers were submitted to the conference. All papers were first subjected to a scientific and technical review, which included determining the content similarity index using specialised software. Subsequently, 142 papers adhering to the technical guidelines and with an acceptable similarity index were double-blind peer-reviewed by reviewers drawn from the scientific committee and external experts depending on the subject matter. Following the review process, 129 full paper submissions were accepted for the conference. Of the papers accepted for presentation at the conference, 113 full papers were included in the conference proceedings.

The Organising Committee of the SSIRC would like to thank the scientific committee, subject chairs, external reviewers, session chairs, staff from OU and presenters for their contribution to the conference.

We trust that the first hybrid conference was an insightful and fruitful experience, contributing to research inspiration.

Prof J Surujlal

SSIRC Co-chair

On behalf of the organising committee

Executive Dean: Faculty of Economic and Management Sciences

North-West University

INSTITUTIONAL CONTRIBUTIONS

A total of 113 full papers were included in the proceedings after the double-blind peer review process. The contributions of papers were received from 22 different national and international institutions, which is depicted in Table 1. The host institution, NWU contributed 29.4% of the full papers in the conference proceedings with 70.6% of the contributions by other institutions. Thus, the proceedings adhere to the DHET criteria that more than 60% of papers have to be from other institutions.

ABSTRACT

The purpose of this study was to assess the effectiveness and efficiency of the Internal Audit Activity (IAA) within South African Police Services (SAPS) and how effectiveness and efficiency could be measured. This is important because IAA is a key pillar of good governance that provides all stakeholders with an independent view on whether the organisation has an appropriate risk and control environment. A quantitative research method was used in conducting this study. Data was collected from previous studies, followed by a questionnaire distributed by hand and email to 100 participants. The SPSS version 25.0 for Windows was used to analyse data. The findings of the study found that barriers that impede effective functioning of other IAA in the public sector are not necessarily barriers to SAPS IAA. The study further indicated that SAPS IAA carefully planned their audits by way of spreading audit resources across all phases of the audit, providing adequate supervision and issuing clear and concise audit reports. The study confirmed that SAPS IAA reporting functionally to the audit committee comprises competent members with mixed skills and experience, which is in line with Institute of Internal Auditors (IIA) standards. Further, it was confirmed that IAA is considered effective when it completes all audits in the audit plan within the budgeted timeframe and complies with its own approved audit manual, methodology and Internal Audit Charter. When IAA has qualified and experienced staff with sound knowledge of the business, and when the audit plan is a risk-based audit plan, covers assurance and consulting engagements, it is regarded as effective. When IAA incorporates inputs from various stakeholders in developing the three-year rolling plan and annual audit plan, it is deemed effective. Continuous affiliation to the professional bodies, appointing auditors with various backgrounds, skills and experience could make SAPS IAA one of the best departments in the public sector. Management should create an environment conducive for IAA to execute its duties and enable IAA to deliver on its commitment objectively and independently.

Keywords: Internal Audit Activity, efficiency, Institute of Internal Auditors, effectiveness, South African Police Service, Internal Auditors, Audit Committee.

INTRODUCTION

Globally, organisations experience rapid change in the business environment which are economic changes, regulatory requirements and technological advancements. Internal Audit Activity (IAA) is part of the organisation and should not be static when changes occur in the organisation. For it to be relevant and continue to provide value-added services, it should take the direction the

organisation is taking because IAA is a key pillar of good governance that provides all stakeholders with an independent view on whether the organisation has an appropriate risk and control environment.

SAPS is a public service institution, which renders services in terms of preventing and combating crime, investigating crime and providing safety and security services to South Africans. Its IAA strategy should always be aligned with organisational strategy to assist SAPS achieve its goals and objectives.

IAA serves as eyes and ears of management and to be effective and efficient, full support from management and the audit committee is required. This is supported by the results of the study conducted by Mihret & Yismaw (2007) who state that internal audit quality, support from management and auditee attitudes towards the work of IAA can be the basis or fundamental principles of IAA effectiveness. The study further cited that support from management is vital by means of providing IAA with the necessary resources, which are financial, human and physical, required to carry out its audits.

When sufficient resources are made available, IAA is able to increase the audit coverage, and it strengthens the independence and objectivity of IAA. Morgan (2009) supports this notion by stating that when IAA is allocated insufficient resources, it is an indicator of lack of management support or a sign of not understanding the role of internal audit and benefits that management derive from IAA.

The main responsibility of IAA is to provide management with assurance on the adequacy and effectiveness of controls, risk management and governance processes instituted and implemented by management. The other responsibility is to establish if public funds are used within specified areas, and where there are deficiencies, a report is compiled with value-add recommendations for management to implement (Goodson 2012; Mory et al., 2012). This also assist the organisation to achieve a desired outcome/report from the AGSA, which is unqualified audit opinion. A well-equipped IAA plays a crucial role in assisting the organisation to fight allegations of fraud and corruption, therefore it is easier to achieve this and to get a clean audit report when the organisation has effective and efficient IAA.

The study assessed the effectiveness and efficiency of IAA within SAPS and how such effectiveness and efficiency could be measured. The results of the study conducted by other researchers revealed several challenges that makes IAA to be ineffective and inefficient. A study by Onumah and Krah (2012) found that insufficient human and financial resources makes it difficult for IAA to carry out its mandate. This notion is supported by Adel (2011) that there is a huge shortage of internal auditors in most IAA in the public sector.

LITERATURE REVIEW

This paper commenced with the introduction in the previous section, this section analyses a summary of related literature reviewed on the effectiveness and efficiency of internal auditing. It continued by highlighting the methodology applied, results and discussion of the study. After presentation of the findings, this section is concluded by providing conclusion and recommendations.

Internal Auditing

There is a huge complaint in the context that the performance of some of IAA within the South African public sector does not meet the expectations of the society. This could be because of a lack of effective audit committees, shortage of human and financial resources, non-compliance with IIA standards and lack of support from management. As a result of these challenges, many organisations are regarded as ineffective and inefficient as it becomes difficult to execute their mandate. Most organisation face financial crisis, new laws and regulations that emerge in the business environment, and this makes internal and external stakeholders to place many requirements on the IAA (IIA, 2016). As IAA plays a critical role in the governance framework, there has been an excessive increase in the requirements placed on the IAA.

IIA (2010) states that the quality of an IAA is mainly related to its effectiveness, efficiency and measuring effectiveness of IAA is a complex task to do. Effectiveness is defined as the magnitude to which agreed objectives are achieved, while efficiency is described as the degree to which allocated resources have to be deployed to achieve a certain objective.

IIA (2010) makes provision for indicators that can be used to measure the effectiveness and efficiency of IAA in an organisation. These were the indicators used to measures IAA effectiveness.

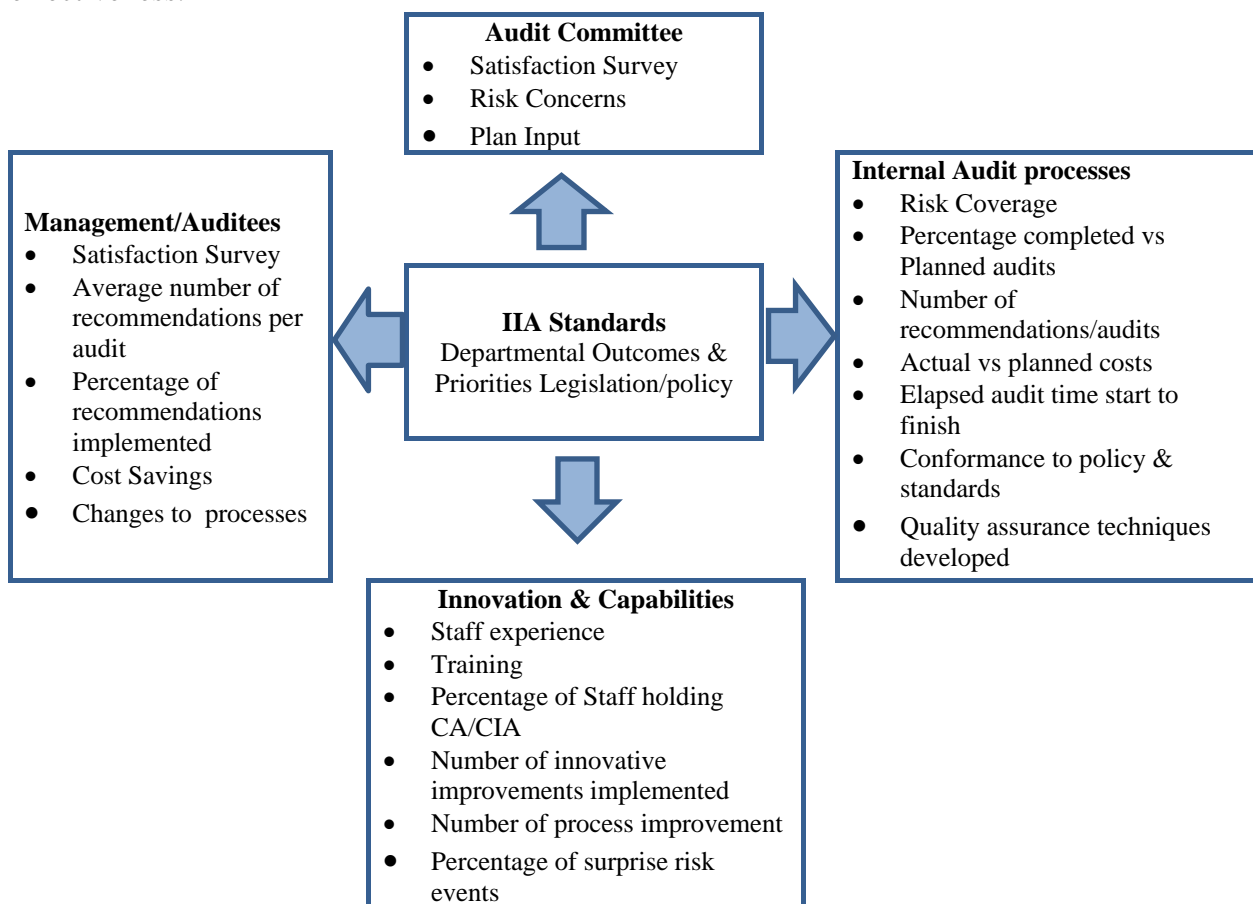

Figure 1: Effectives and efficiency indicators

Source: IIA (2016)

Internal auditors worldwide are required to affiliate with a professional body, which is the Institute of Internal Auditors established in 1941 in Florida, USA. The institution established the IIA SA Chapter in 1964 and transitioned from Chapter to National Institute in 1983. This institution has developed an International Professional Practices Framework (IPPF) for effectiveness of internal audit. The aim of this framework is to effectively support and guide everyone who is in the audit profession. The IIA developed the Standard for the Professional Practice of Internal Auditing, which incorporates the definition of internal auditing (Chapman & Anderson, 2002). “Internal auditing is defined as an independent and objective assurance and consulting activity designed to add value and improve the organisation’s operations. It helps an organisation to accomplish its objectives by bringing a systematic, discipline approach to evaluate and improve the effectiveness of risk management, control and governance processes” (IIA, 2017).

A study conducted by Savcuk (2007) found that only efficient IAA can execute its mandates or tasks properly. Furthermore, the study indicated that the efficiency of IAA depends on its independence and objectivity; the experience, skills and professional qualification of IAA staff; the internal audit strategy and value added to improve the organisation’s operations (Savcuk, 2007). The results of this study are in line with Figure 1, developed by IIA to measure effectiveness and efficiency of IAA.

A study conducted by Ali et al. (2007) showed a huge challenge IAA face is insufficient resources to execute its mandate. This notion is supported by another study by Ahmad et al. (2009), which revealed that insufficient funding was the root cause of IAA poor performance in Malaysian government departments. However, studies conducted by Ali et al. (2007), and Alzeban and Gwilliam (2014) support the notion that when IAA is well resourced and has sufficient number of staff to execute the audit plan, it is highly likely to be effective.

Alzeban and Gwilliam (2014) found that independence or objectivity is the main element in ensuring effectiveness of IAA. Their study identified lack of independence and objectivity as the main obstacle to good performance of internal audit in most developed countries. This suggests that reporting lines of internal activity are critical and should be aligned with IIA standards, which allow for reporting to the highest level in the organisation.

A study by Menza, Aga and Jerene (2019) on determinants of IAA in the Ethiopian public enterprises contradicts results of other researchers. The results indicated that having sufficient human and financial resources, qualified internal audit staff and approved IA charter do not significantly predict effectiveness of IAA. The respondents also disagreed with the notion that an independent internal audit significantly predicts effectiveness of internal auditing.

Regulations of Internal Audit Activity in the Public Sector

In South Africa, internal audit activity (IAA) is established in the public sector to meet the requirements of Section 38(1) (a) (ii) of the PFMA Act of 1999. This Section further requires that the established IAA must be under the direction and control of the Audit Committee (AC). In support of the PFMA requirement, the National Treasury has developed an internal audit framework that serves as a guide for the development and functioning of internal audit activities in the public sector.

Theoretical Framework

Theory adopted for this study is Agency Theory. In Agency Theory, owners delegate authority for making decisions to the managers, and managers perform certain tasks as agents on behalf of the owner. At SAPS, auditors are appointed by executives and operate as audit committee representatives, expected to assess the work of the executives and give feedback to the audit committee. IAs, therefore, are regarded as agents who monitor the performance of the following stakeholders: executives, the board, and audit committee. Agency problems arise where the audit committee is inefficient, and management are so powerful and can influence the IA.

Internal Auditing of SAPS

To fulfil the requirements of the PFMA Act of 1999, SAPS has established IAA in 2003 at the national level and expanded its wings to all nine provinces in 2007. The fixed establishment for the component is currently at 144 internal auditors, comprising junior, middle, and senior managers. For the financial year 2022/2023, the component internal audit is operating at a budget of approximately R25 million, which is 5% above the baseline or 5% more compared to the previous financial year's budget. This is in line with the study by Alzeban and Gwilliam (2014), which found that effectiveness of IAA is likely to be high when IAA is provided with sufficient financial and human resources.

SAPS IA is expected to provide management with assurance on the adequacy and effectiveness of internal controls, risk management and governance processes on all SAPS divisions, components, sections and police stations. Amongst internal audit staff, there are four members qualified as Certified Internal Auditor (CIA), three members as Certified Fraud Examiner (CFE) and one member as Certified in Control Self-Assessment (CCSA); the rest hold university degrees and diploma qualifications. This is in line with the study by Savcuk (2007), which hold that the efficiency of IAA depends on the skills, experience and professional qualifications of internal audit staff. The results of a study conducted by Abu-Azza (2012) showed there is a need for internal auditors to be highly qualified if a high level of effectiveness is to be achieved. Abdolmohammadi (2009) supports this notion by stating that CIAs comply with IIA standards in Anglo-Saxon countries when carrying out their audit assignments.

The Role of Internal Audit Activity in SAPS

IAA is responsible for providing assurance and consulting services in the organisation. This is clearly stated in the definition of internal auditing provided earlier. IIA (2010) states that assurance services involve unbiased examination of evidence to reach conclusion on the process being assessed. Internal audit should be involved in analysing compliance with governance processes and practices and make recommendations on whether those governance processes are suitable for organisation needs (Marks, 2012).

Consulting services are advisory kind of services aimed at improving organisational processes (IIA, 2010). In situations where management is struggling to develop governance processes and procedures, IAA provides advice on how organisational governance processes and procedures should be developed and implemented.

Analysis of Enterprise Risk Management, Controls and Governance Processes.

“Enterprise risk management is defined as structured, consistent and continuous process across the whole organisation for identifying, assessing, deciding on responses to and reporting on opportunities and threats that affect the achievement of its objectives” (IIA, 2013). Arena and Sarens (2015) imply that IAA has a key role to play in the development, implementation and operations of enterprise risk management. However, the study further indicated that too much involvement in enterprise risk management may threaten the independence and objectivity of IAA. A study by Abdurrahman et al. (2020) supports the notion that IAA may play a critical role in the development and implementation of enterprise risk management.

In Malaysia, it was found that most of organisations are struggling to survive due to poor enterprise risk management. A study by Sottanizadeh et al. (2016) recommended that all firms and government institutions should involve IAA in the development and implementation of risk management. SAPS has a fully functional risk management component that facilitates the risk management process across the entire organisation and develops a risk management profile of each business unit. The function of risk management falls under second line of defence in the combined assurance framework (IIA, 2013).

The departmental risk management profile includes both strategic and operational risks, as well as existing controls to manage identified risks. When this process is completed, IAA is involved in reviewing the risk management profile and provides management with information on whether the risk management profile is adequate and effective or not.

IIA (2013) defines corporate governance as the combination of processes and structures implemented by the board to inform, direct, manage and monitor the activities of the organisation towards achieving its objectives. According to Irwan Adimas and Achmad (2019), good corporate governance increases the effectiveness and operational efficiency of an organisation and, as part of corporate structure, an audit committee is established to monitor the performance of management of the organisation. The study concluded that internal audit can play an important role in corporate governance of the organisation.

A study by Zou (2019) implies that a healthy organisation is built on solid corporate governance. The study further revealed that internal audit is an integral part of corporate governance as it forms part of determining the integrity and security of the corporate governance structure. Internal audit can promote effective corporate governance by means of evaluating the organisation’s operating conditions and effective utilisation of resources. Good corporate governance also enhances or strengthens the independence and objectivity of IAA. Consequently, it is important for IAA to be part of corporate governance structure.

Control is defined as any action taken by management to manage risk and increase the possibility that set objectives and goals will be achieved (IIA, 2013). The Committee of Sponsoring Organisation (COSO) developed an internal control framework to guide management of the organisation on the development and implementation of internal controls. The COSO framework is used and recognised worldwide and comprises of five components, which are: control environment, risk assessment, control activities, information and communication, and monitoring (Graham, 2015).

An organisation benefits when internal controls are properly developed and implemented by means of securing the entity's assets, providing reliable financial reporting, complying with laws and regulations and preventing and detecting fraud. An important role internal audit plays in internal control is reviewing such controls and giving assurance on whether controls are adequate and effective or not.

METHODOLOGY

The research method applied for this study is quantitative research method. Tewksbury (2009) implies that this method could make correct or true predictions. This method was chosen because it makes use of questionnaires for collecting data and allows large amounts of numerical data to be generalised and analysed statistically. The researcher sourced data from various research participants, analysed, and interpreted the data.

RESEARCH DESIGN

This study employed a descriptive survey research design as it determines and reports the way things are (Khalid & Kuma, 2012). This design provides high quality data; the data collected represented a large population, which made things easier to analyse and draw a conclusion.

SAMPLING METHOD

The population for this study comprised current SAPS auditors, AGSA auditors and Audit Committee members, who were working in SAPS at the time the study was conducted. A simple random sampling method was used in selecting eighty (80) SAPS auditors, sixteen (16) AGSA auditors and four (4) audit committee members. Simple random sampling affords each element in the population an equal chance of being selected (Daniel, 2012). A sample of 100 participants was deemed sufficient for this study.

Research instrument

Cooper and Schindler (2014) mention various instruments that can be used to collect data, such as interviews and questionnaires. Data were collected from various participants using a structured questionnaire.

Data collection

Permission was given by SAPS National Commissioner to conduct the study. One hundred (100) questionnaires were distributed to the 100 selected members who constituted the sample, delivered personally to participants based in Pretoria and by email to those outside Pretoria. Of the 100 questionnaire, 91 responses were received, 60 from SAPS employees consisting of senior and middle managers, 20 from SAPS internal auditors, 7 from AGSA auditors and 4 from audit committee members. All 91 responses received were fully completed and valid.

Data analysis

Data collected were captured on Excel and exported to Statistical Package for Social Sciences (SPSS) version 25 for Windows for analysis. Validity and reliability tests were conducted to assess for the internal consistency of the questionnaire items. This was done by an expert in the field through scientific verification applying normality tests, skewness, and kurtosis of the factors.

RESULTS AND DISCUSSION

Normality Test

From the descriptive statistics, the skewness and kurtosis values were achieved, which indicates whether the data are normally distributed or not. According to Hair et al. (2016), normal distribution is acceptable when the skewness and kurtosis values are in the range of +/-3. The test of the results is shown in Table 1. Subsequently, the data were determined as normally distributed since the values of skewness and kurtosis were in the range of +/-3 for each variable. Table 1 depicts the normality results of skewness and normality values.

Table 1: Normality Analysis

| Variables | Normality Analysis | | | |
|---|--------------------|-------|--------------|--------------|
| | Obs | Items | Pr(skewness) | Pr(Kurtosis) |
| Examine the efficiency and effectiveness of internal audit activity | 91 | 8 | 0.0066 | 0.0066 |

RELIABILITY AND VALIDITY TESTS

Data were tested for reliability and validity as reflected in Table 2. Validity is the degree to which dimension yields true score of the variable under investigation (Block & Block, 2005). To establish reliability and accuracy of the measuring instrument, Cronbach's alpha coefficients were calculated and coefficients of 0.70 or higher were considered to give sufficient evidence of reliable scale (Hair et al., 2014), but values of 0.5 or lower are regarded as acceptable (Loewenthal, 2004).

The alpha values for the variables indicated that the items formed a scale of reasonable internal consistencies in their reliability. The correlation for the item in the constructs was between the value of 0.7 and 0.83. The item, therefore, correlate adequately in the constructs, confirming the theoretical and empirical evidence of the items from the literature.

Table 2: Cronbach's Alpha Reliability Test

| Variables | Cronbach Alpha |
|---|----------------|
| Examine the efficiency and effectiveness of Internal Audit Activity | 0.838 |

Analysis of Response to the Research Objective

The purpose of the research was to assess the effectiveness and efficiency of SAPS IAA and how such effectiveness and efficiency could be measured. The mean, standard deviation and frequency distributions were calculated to describe the sample. To summarise the sample in the study, response categories on the five-point Likert scale for both the dependent and independent variables were categorised as follows: responses from $1 \leq \bar{x} < 2.5$ were categorised as disagree; $2.5 \leq \bar{x} < 3.5$ categorised as neutral; and $3.5 \leq \bar{x} \leq 5$ were categorised as agree.

Results of the study indicate that SAPS internal audit meets all key performance indicators used to measure effectiveness and efficiency of IAA. Therefore, the study results qualify SAPS internal audit as effective and efficient. Most of the participants were in agreement with the notion that SAPS internal audit staff are experienced, qualified, and undergo necessary training to enhance their knowledge and skills.

Table 3: The Analysis of the Extent of SAPS IAA Efficiency and Effectiveness and measurement of such Effectiveness and Efficiency

| | Strongly disagree | | Neither agree nor disagree | | Strongly Agree | | | |
|---|-------------------|--------------|----------------------------|--------------|----------------|----------------|------|----------|
| | disagree | Disagree | Disagree | Agree | Agree | Agree | | |
| Planned audits not completed | 18 20.0% | 33 36.7% | 11 12.2% | 17 18.9% | 11 12.2% | 90 100.0% | 2.67 | Disagree |
| Utilisation of technology to cut costs | 3 3.3% | 3 3.3% | 9 10.0% | 29 32.2% | 46 51.1% | 90 100.0% | 4.24 | Agree |
| Satisfaction survey received from client | 2 2.2% | 4 4.4% | 15 16.7% | 40 44.4% | 29 32.2% | 90 100.0% | 4.00 | Agree |
| IA considers stakeholders' inputs when developing IA plan | 1 1.1% | 1 1.1% | 12 13.2% | 42 46.2% | 35 38.5% | 91 100.0% | 4.20 | Agree |
| IIA appointed experienced staff | 3 3.3% | 1 1.1% | 11 12.2% | 48 53.3% | 27 30.0% | 90 100.0% | 4.06 | Agree |
| Audits not completed within the budgeted time & money | 20 22.0% | 33 36.3% | 20 22.0% | 12 13.2% | 6 6.6% | 91 100.0% | 2.46 | Disagree |
| IIA considers risk assessment when developing IA plan | 1 1.1% | 2 2.2% | 14 15.4% | 43 47.3% | 31 34.1% | 91 100.0% | 4.11 | Agree |
| Staff holding relevant designation | 3 3.3% | 6 6.6% | 20 22.0% | 43 47.3% | 19 20.9% | 91 100.0% | 3.76 | Agree |
| Sufficient training to internal auditors | 3 3.3% | 5 5.5% | 22 24.2% | 39 42.9% | 22 24.2% | 91 100.0% | 3.79 | Agree |
| IA performs assurance audits & quality audit reports | 3 3.3% | 1 1.1% | 1 1.1% | 46 50.5% | 40 44.0% | 91 100.0% | 4.31 | Agree |
| IA performs consulting audits & reports to Audit committee | 4 4.4% | 4 4.4% | 12 13.2% | 43 47.3% | 28 30.8% | 91 100.0% | 3.96 | Agree |
| Supervision & conformance with IIA standards, methodology & IA charter. | 4 4.4% | 6 6.6% | 16 17.6% | 37 40.7% | 28 30.8% | 91 100.0% | 3.87 | Agree |
| Less number of recommendations. | 29 31.9% | 37 40.7% | 14 15.4% | 9 9.9% | 2 2.2% | 91 100.0% | 2.10 | Disagree |
| Total | 94 8.0% | 136 11.5% | 177 15.0% | 448 38.0% | 324 27.5% | 1179 100.0% | 3.65 | Agree |

Adequate supervision of the work of internal audit is provided throughout the audit process. These results are in line with the results of the study conducted by Mihret and Yismaw (2007), which found that internal auditors who are experienced, skilled and have knowledge of the business are vital in making internal audit effective.

Participants indicated that internal auditors perform both assurance and consulting audits and comply with IIA standards, methodologies and IA charter when carrying out their work. Furthermore, departmental risk assessment and inputs from management and other stakeholders are considered when developing the internal audit plan, planned audits are completed within the budgeted time and costs and all audits in the audit plan are completed before the financial year end.

The results also confirmed that internal audit reports to the Audit Committee strengthen independence and objectivity. The results of this study further indicated that SAPS internal audit utilises various technological tools such as Audit Command Language to analyse data and

Teammate software to record and store all audit working papers. This enhances efficiency and effectiveness of SAPS IAA

Table 4: Analysis of Research Objective One - Sample Test (Test Value=3)

| | N | Mean | Std. Deviation | t-statistics | Sig(2-tailed) |
|---|------|------|----------------|--------------|---------------|
| Examine the effectiveness & Efficiency of internal audit activity | 1179 | 3.65 | 1.219 | 18.444 | 0.000*** |

***, **, * on the p-value represent 1%, 5%, 10% respectively.

Table 4 depicts the significant level of responses by participants, relating to their average decision on the effectiveness and efficiency of IAA in SAPS. The results revealed that the average of the respondents agree on the effectiveness and efficiency of the SAPS IAA. Most of the key performance indicators used to measure effectiveness and efficiency of internal audit were adequately in place.

CONCLUSION

The results of this study are in line with most of the literature reviewed regarding the effectiveness and efficiency of SAPS internal audit. The study results also indicate that key performance indicators outlined in the guideline document for measuring the effectiveness of IAA are, indeed, tools that can be used to measure effectiveness and efficiency of each IAA globally.

Though the overall results confirmed SAPS internal audit as effective and efficient, majority of its members the participants do not have professional certifications. Therefore, there is a need for management to encourage internal auditors to study towards professional certifications such as CFE, CIA, CCSA, and CA. The organisation should make bursaries available to all internal auditors or establish a training budget to enable them study towards these professional qualifications.

Continuous affiliation to the professional bodies, appointing auditors with various backgrounds, skills and experience could make SAPS IAA one of the best departments in the public sector. Management should continue to create an environment that is conducive for IAA to execute its duties and to be able to deliver on its commitment.

APPLICATIONS OF RDI TO AGRI PROJECTS AND BUSINESSES' RISK ANALYSIS OVER MANGAUNG METROPOLITAN MUNICIPALITY'S GRASSLAND, SOUTH AFRICA

B.M. Hlalele

Central University of Technology, Free State, Bloemfontein, South Africa

ABSTRACT

Scientists have warned that climate change would occur rapidly resulting in extreme floods and droughts that would adversely affect human lives, economy, and environment. Given the recent drought risk disaster declared in the Free State province of South Africa, Mangaung Metropolitan Municipality (MMM) was selected as it is the only Metropolitan Municipality in the province with large farms in animal and crop husbandry. Data used in this study was collected from an online source Tutiempo. These data were checked for outliers in both precipitation and temperature. All outliers detected were removed and replaced by Expectation maximum algorithm using SPSS. This procedure was followed by stationarity test to avoid spurious results. Due to fact that RDI requires PET and precipitation for computation, Thornwaite method was used to compute PET from DrinC software. The aim of this study was to determine the climatic changes in MMM's vegetation using a 3-month Reconnaissance Drought Index (RDI). The results revealed a significantly decreasing Mann Kendall's trend which implies intensifying drought events over MMM. This situation threatens MMM vegetation and maize production that support human lives. The study therefore has provided a basis for proactive planning against drought events in the near future, through policy and legislation enforcement, sparingly water use and community outreaches in water importance and use.

Keywords: Climate change, RDI, grassland biome, vegetation, drought, disaster

INTRODUCTION

The flora of South Africa is extremely rich in diversity both in species and ecosystems (Burton et al. 2011; Mostert, 2017). This country is one of the 25 most diverse countries and ranked as the 5th highest in plant species in the world (Reyers *et al.* 2001). These authors assert that the grassland in this country covers 26% of South Africa and shows some diversity where multiple rare and endemic plants are found. The grassland biome of this country covers the most agriculturally productive area (Swanepoel, 2006). This area is the country's major source of beef, crops, and dairy. It also serves as an area where majority of the country's population lives (Swanepoel, 2006). However, factors such as drought, soil erosion, invasion by exotic species and anthropogenic activities pose a serious threat to the existence of this biome. Due to these threats, this biome has been identified as critically endangered, based on the degree of habitat loss, fragmentation aggravated by the vast changing climate (Cerling *et al.* 1997). Thus, ecosystems are increasingly prone to local discontinuities, extreme events, extinction of species, decline of intra-specific diversity and the reorganization of the existing communities rather than to synchronous shifts of whole vegetation units (Glick, Staudt and Stein, 2009; Sabatini *et al.* 2014). According to Bredenkamp *et al.* (2006) about 60 to 80% of South African grasslands are already irreversibly

transformed by activities such as agriculture and rapid urbanisation. In addition to this, Low and Rebelo, 1998; Reyers *et al.* (2001) state 2.3% of the grasslands are currently conserved while International Union for Conservation of Nature (IUCN) recommends 10% of this biome to be conserved.

Climate is one of the primary controls on species diversity and distribution globally and changes in climate have significantly modified biodiversity. At the Kyoto climate summit in 1997, various highly recognized scientists issued world scientists call of action. They stated, “*climate change will accelerate the appalling pace at which species are now being extirpated especially in vulnerable ecosystems*” (Dirzo and Miranda, 1991; Grewley, 1986). Similarly, the Millennium Ecosystem Assessment (2005) and Kiraso (2012) also forecasted that at the end of the 21st century, climate change and its impacts may be dominant drivers of biodiversity loss and the change in ecosystem services globally where there may be adverse impacts from (i) rise in sea level, (ii) an increase in severity and frequency of extreme weather conditions and (iii) increase in temperatures. McLachlan, Hellmann and Schwartz (2006; Julia *et al.* 2011) also suggested based on compelling evidence that climate change will be a significant driver of extinction. Unfortunately that is the case, climate change impacts fall disproportionately on the world’s poorest, most marginalized communities, especially those which are wholly and directly dependent on a stable and consistent supply of local natural resources for daily subsistence and trade because they lack alternative means of income and livelihoods and they are unable to sufficiently adapt to changes of climate (Westerman, Oleson and Hams, 2013; Tompkins and Adger, 2004; IPCC, 2007; UNFPA, 2009). These communities often suffer from a vicious mix of poverty, poor public health, and high population, all of which together hinder resilience and adaptation to climate change. The instability of natural resources due to climate change in such communities highly reliant on natural resources therefore has devastating effects on food security, sustainable development, human wellbeing, and household income (Baxter, 2014; Causton, 1988; Tagestad, 2010) Hlalele, 2016). Moreover, there is a widespread alarm on the rate of biodiversity loss due to many factors such as anthropogenic activities and climate change. This accelerating loss of biodiversity in those vulnerable ecosystems results in unsustainable human-nature interactions hence food insecurity and other environmental problems (McDonald and Service, 2007). The uncontrolled exploitation of resources by communities that are highly reliant on natural resources is likely to bring about adverse population declines and in the long run the extinction of some species. This will in turn result in many changes in the habitat dynamics through the loss of seed dispersers, pollinators, granivores and frugivores (Dirzo and Miranda, 1991; Podani, 1986; Grime, 1979; Bordi and Sutera, 2007). Already to be seen or to be further expected are changes on all levels of ecosystem; on a species level, food chains, decomposition processes and overall changes in the dynamics of the ecosystems (Hughes *et al.* 2003). Thus, ecosystems are increasingly prone to local discontinuities, extreme events, extinction of species, decline of intra-specific diversity and the reorganization of the existing communities rather than to synchronous shifts of whole vegetation units (Glick, Staudt and Stein, 2009). A changing climate will probably also affect some essential soil functions too. Hughes *et al.* (2003) also reports that the climate change has left visible marks within different ecosystems all over the world and the expectation is for the warning trend to continue or even increase with time.

In South Africa, the biodiversity hotspots in the succulent karoo and cape floristic region for instance are already experiencing major vegetation shifts due to climate change effects which will

eventually exceed the natural response of a large number of species (Hannah, Midgley, Lovejoy, Bond, Bush, Lovett, Scott and Woodward, 2002: Bureau of Land Management, 1999). Vulnerability to climate change involves both social and ecological factors and any efforts to reduce and build long term resilience must target both to ensure that resource dependent communities are able to cope with effects of climate change such that they are less affected or can easily recover from the effects of climate change (Tompkins and Adger, 2004: Grant, 1968). According to Kiraso (2012), climate change affects various aspects of the socio-ecological system including disease coverage, biodiversity, land degradation and the availability of water. SADC sub region is among the most affected regions in the world. Rural communities in Southern Africa are highly vulnerable to climate change because of their extreme poverty of a vast majority of its dwellers, high existing disease burden, low levels of education, frequent natural disasters such as drought, agricultural systems that are highly dependent on rainfall and the community's high and direct dependence on natural resources (Kiraso, 2012: Mandal and Joshi, 2014: Castillon, *et al.* 2015: Akira, 2014). The current study area lies in the outskirts of Thaba Nchu Township. In 2015, the South African Free State province was one of the five provinces that were first declared drought disaster struck. In addition, in a study conducted by Hlalele (2016b) in Mangaung Metropolitan Municipality (MMM) on spatio-temporal climate change risk assessment, results revealed most vulnerability to climate change explained by rural communities. In the light of all the above, the current study aimed to determine the climatic changes in MMM's vegetation using a 3-months Reconnaissance Drought Index (RDI) for improved proactive agricultural and water resources planning.

METHODS AND MATERIALS

Data quality control

The study used monthly precipitation and average temperature from Bloemfontein airport station in Bloemfontein obtained from an online source. Both the data sets were checked for outliers using the following outlier range formular.

$$(\mu - \alpha; \mu + \alpha) \dots \dots \dots \text{Eqn [1]}$$

Where μ denotes mean in both precipitation and temperature data sets and α denotes standard deviation

The outliers were removed and gaps filled with Expectation Maximum (EM) algorithm for missing data using SPSS. These two data were collected from 1977 January to 2017 October. The November and December values were estimated together with outlier gaps from EM. In order to ensure the reliability and validity of the final results and avoid spurious results, three stationarity tests (i) Dickey-Fuller, (ii) Phillips-Perron and KPSS were conducted for both precipitation and temperature. Reconnaissance Drought Index (RDI) is a water balance drought index that uses Potential Evapotranspiration (PET) and precipitation as basic input parameters. The researchers used Thornwaite method computed from DrinC calculator developed by in Greece. This method used only the average temperature to compute PET.

We calculated RDI on 3-month time steps from October-September over 41 hydrological years. RDI was computed from gamma probability distribution fitting. RDI is a climatic change indicator and used for drought detection as an early warning system for drought disasters (Tigkas *et al.*

2015). Given the focus of the current study which assesses the climate changes over MMM vegetation, a 3-months RDI time series was considered. To detect if any changes occurred in the RDI series, a non-parametric Mann Kendall's trend test was used.

RESULTS

Table 1: Stationarity test for monthly precipitation (mm)

| Test statistic | Tau (Observed value) | Tau (Critical value) | p-value (one-tailed) | alpha |
|----------------------|----------------------|----------------------|----------------------|-------|
| Dickey-Fuler test | -10.589 | -0.889 | < 0.0001 | 0.05 |
| Phillips-Perron test | -9.928 | -1.941 | < 0.0001 | 0.05 |
| | Eta (Observed value) | Eta (Critical value) | p-value (one-tailed) | alpha |
| KPSS test | 0.380 | 0.458 | 0.082 | 0.05 |

Table 1 shows data quality assessment before more detailed analysis could take place. Three stationarity tests were used in precipitation data to check if the data was stationary to avoid incorrect and misleading results. The Dickey-Fuler, Phillips-Perron and KPSS tests were used to complement one another. The results showed that the precipitation data was indeed stationary with p-values less than $0.0001 < 0.05$ significant level.

Table 2: Stationarity test for maximum monthly average temperature ($^{\circ}$ C)

| Test statistic | Tau (Observed value) | Tau (Critical value) | p-value (one-tailed) | alpha |
|----------------------|----------------------|----------------------|----------------------|-------|
| Dickey-Fuler test | -12.826 | -0.889 | < 0.0001 | 0.05 |
| Phillips-Perron test | -2.898 | -1.941 | 0.004 | 0.05 |
| | Eta (Observed value) | Eta (Critical value) | p-value (one-tailed) | alpha |
| KPSS test | 0.034 | 0.458 | 0.968 | 0.05 |

Given that RDI requires two input parameters for computation, the average maximum temperature was also tests for stationarity and the data was found stationary as shown in table 2 above.

Figure 1: Standardised 3-Months Reconnaissance Drought Index (RDI)

The 3-month time scale in RDI can be linked in agricultural drought which affects crops and vegetation (Kanellou *et al.* 2012). Figure 1 above shows the plot of RDI-3 over 41 years from 1977-2017 in MMM. A non-parametric trend test (Mann Kendall test) was applied to detect if any monotonic increasing or decreasing trends existed in the RDI-3. The results showed decreasing climatic changes specifically intensifying drought episodes in MMM with a p-value = < 0.0001

and a Sen's slope of -0.001. Drought intensity measures how far precipitation is below the average (Abdulmalek *et al.* 2013). This drought parameter is determined from the concept of Standard Total Accumulative Dry (STCD) which is the total summation of all RDI with negative values. In order to quantify the intensity drought researchers, use Average drought Index derived from the following equation:

$$ADSI = STCD/N \dots\dots\dots Eqn [2]$$

Where N, denotes the numbers of uninterrupted consecutive months with negative RDI values. The results showed N=60, STCD= -195, hence ADSI=-3.25. when using table 3 below, the study area is classified as experiencing a special drought regime with a significantly increasing drought intensity. According to this study, the 2015 drought is the second after 1994 as shown in figure 1 above.

Table 3: Classes of RDIst

| | |
|-------------------|-------------|
| Special Wet | >2 |
| Extremely Wet | 1.6 – 2 |
| Severely Wet | 1.3 – 1.6 |
| Medium Wet | 0.8 – 1.3 |
| Small Wet | 0.5 – 0.8 |
| Normal | -0.5 – 0.5 |
| Small Drought | -0.8 – -0.5 |
| Medium Drought | -1.3 – -0.8 |
| Severely Drought | -1.6 – -1.3 |
| Extremely Drought | -2 – -1.6 |
| Special Drought | <-2 |

Source: Gholamreza *et al.* 2013

CONCLUSION

Mangaung Metropolitan Municipality is fully covered with grasslands that supports livestock and serves as a habit for most animal species (Rebelo, 2001). This area is found in the central region of South Africa with most animal population and serves as the *breadbasket* of the country through the highest production of maize. The results of this study indicated a threatening behaviour towards MMM vegetation and maize production that support human lives. The study therefore has provided a basis for proactive planning against drought events in the near future, through policy and legislation enforcement, sparingly water use and community outreaches in water importance and use.

A CLUSTER-BASED FACTOR ROTATION IN ASSESSING AGRICULTURAL PROJECTS' EXTERNAL RISK AND CLIMATE CHANGE VARIABILITY OVER LERIBE DISTRICT, LESOTHO

B.M. Hlalele

Central University of Technology, Free State, Bloemfontein, South Africa

ABSTRACT

Climate change is probably the most complex and challenging environmental problem facing the world today. Currently, the intriguing questions include weather uncertainties, persistent climatic abnormalities, such as floods and drought events, rampant environmental degradation, and eminent food insecurity. The current study therefore aimed at assessing how climate is current varying with time thereby affecting agricultural business activities. For this study precipitation dataset was obtained from an online NASA database for Leribe district in Lesotho. Both non-parametric Pettitt homogeneity test and outlier detection were conducted by XLSTAT and SPSS respectively for data quality control. A drought Monitoring and Prediction software was used in the computation of Seasonal Standardised Precipitation Index (SPI-3) and drought severity. A non-parametric Mann Kendall's test was used for monotonic trends patterns detection over the precipitation time series, where there was no trend in the entire time series but a statistically significant decreasing trend in SPI-3 ($p < 0.00013$). Exploratory factor analysis was employed to cluster months into new seasons. Four factors were extracted using a greater than 1 eigenvalue rule, with a chi-square p-value of ($p=0.915$). The new seasons depicting new clusters were subjected to a confirmatory factor analysis where model fit indices; Comparative Fit (CFI), Tucker-Lewis (TLI) and Root Mean Square Error of approximation (RMSEA) indices were all within expected threshold levels. The cluster-based rotation revealed new seasons where Spring was found be longer and extended into Summer, a shorter Autumn and fragmented Winter season all with severe drought episodes. The study then recommends a paradigm shift in crops growing times and cultivators to cash crops that drought resistant.

Keywords: Cluster-based rotation, climate change, variability, risk, drought, SPI

INTRODUCTION

A period in time whereby conditions are drier than usual and there is a lesser amount of rainfall than normal for a long period of time; for several weeks, months and even years which lead to water-related problems is defined as drought (Praveen, Ramachandran, Jaganathan, Krishnaveni, & Palanivelu, 2016). Nevertheless, there is no specific definition of drought; but it can be classified into four essential types. In this study, drought is described as a severe state which is has undesirable dry spell which has negative impacts on the economy, society, and environment. The four essential types of droughts are: meteorological drought, hydrological drought, agricultural drought and socio-economic drought. (i) Meteorological drought is simply the degree of dryness compared to normal conditions and this is irregular over time and certain regions (Olivares Campos, 2016), (ii) hydrological drought on the other hand is deficient rainfall which results into grave reduction in run-off streamflow, inflow into storage reservoirs and revitalizing of

groundwater (Orlando Olivares & Zingaretti, 2018), (iii) Agricultural drought refers is a deficit of soil moisture to sustain plants and livestock in that way causing weakened growth and reduced produce (Tefera, Ayoade, & Bello, 2019) and Socio-economic drought is a period in time whereby human activities are negatively affected by reduction in water availability and precipitation. (Praveen et al., 2016). As much as all these types of droughts have a linkage, one leads to another and every now and then overlaps; thus, agricultural drought is regarded as of prime importance and a roadmap in this study. The figure 1 below illustrates the interrelationship of the types of droughts.

Even though numerous continents around the world pass through the separation between two hemispheres, Africa is the only continent that lies within them all and is affected by numerous climatic conditions. (Roman-Cuesta, 2007). As a result, this continent receives conventional rainfall. (Choi, An Prof., Yeh, & Yu, 2013). This also escalates to different climatic conditions such as El Nino. El Nino is a recurring climate pattern which is caused by changes in temperatures of water by warming the eastern Pacific, and therefore affecting the global climate. (Ali & Ali, 2011). This natural occurrence is responsible for exacerbating drought events in the southern hemisphere. (Ali & Ali, 2011). In accordance with Keil, Zeller, Wida, Sanim, & Birner (2008), drought is a resultant of the shifting, changing weather patterns. On the other hand, it is also a belief that droughts chiefly transpire because of natural occurrences due to the earth and atmospheric systems. In contrast, Granzow-de la Cerda, Lloret, Ruiz & Vandermeer (2012) are of the belief that no one knows for sure why droughts occur, but many scientists believe that there is an affiliation between drought occurrence and El Nino events. Thorough comprehension of the relationships between droughts and repeated changes in high and low pressures from one side of the Pacific to the other linked with La Nina allow scientists to formulate improved predictions of this calamitous drought hazard. (Ryu, Svoboda, Lenters, Tadesse, Knutson 2010). Both El Nino and La Nina form the El Nino-Southern Oscillation (ENSO) cycle. ENSO is a recurring climate pattern whereby temperature fluctuate between the ocean and atmosphere in the east-central Equatorial Pacific, approximately between the International Date Line and 120 degrees West (Olivares Campos, 2016). Nevertheless, these two events happen every 2-7 years with El Nino events occurring more often than those of La Nina (Tefera et al., 2019). There has been a rising trend in global weather disasters since 1980, and with extreme climatic events such as droughts. (Orlando Olivares & Zingaretti, 2018). Comprehending phenomena such as ENSO is pivotal because of the possibility that it could cause an enormous loss of property, destruction to the environment and the loss of human life. Conjectures by ENSO, tracing and monitoring is of a significant role to insurers, government authorities and other pertinent stakeholders for drought management for proactive planning against unfavourable impacts such as acute climatic changes like drought events. (Praveen et al., 2016). Sunspots could also be another source associated with drought. Sunspots commonly last for a period of approximately 11 years. (Minckley, Roulston, & Williams, 2013). They are described as cool surface areas on the sun that are visible in pairs and are darker in comparison with other parts of the sun. These spots have a strong magnetic field and rotate like a giant hurricane. (Mèthy, Damesin, & Rambal, 1996). These authors also affirm that several authors have acknowledged that sunspots have impacts on temperature, precipitation, length of growing seasons, air circulation, atmospheric pressure, high altitude, wind speed and other natural phenomena around the world. Furthermore, Xiao & Zhuang (2007) construct solar activity as a main cause of cyclic deviations of the global climate through triggering of the

evaporation processes. Scientists have also shown that sunspot numbers and drought events are correlated. For instance, during solar activity- drought events take place at solar maximum (Solheim, Stordahl, & Humlum, 2011). This occurrence is related to climatic conditions where temperatures become high during solar maximum (Minnis, 1958). Solar energy is the principal energy source as well as control on evaporation; therefore, distributions of insolation and evaporation are strongly linked. (Siingh et al., 2011). The energy from the sun is the central source of energy present for heating the surface of the planet earth. This energy supplied by the sun is an outcome of its activity and it differs with time. The major cycle of the sun is eleven years. The major cause of drought events is believed to be the solar activity (Ghormar, 2014). The coefficient of correlation between insolation and evaporation ranges between 0.820 and 0.948 and values of the calculated solar radiation are used in the computation of the Potential Evapotranspiration (PET) in Penman equation (Abarca del Rio, Gambis, Salstein, Nelson, & Dai, 2003). The solar radiation that falls on the earth's surface depends on the distance it travels to the object and the angle at which rays hit an area or object. (Méthy et al., 1996). The universal law for the intensity of radiation, distinctively the sine law of sunlight states that the sunlight always strikes the high latitude obliquely, so it spreads out more and is less intense. (Minckley et al., 2013).

DROUGHT IMPACTS

There are several impacts of drought, and these include: mass starvation, famine and a pause or sometimes an end to economic activities particularly in areas where rain fed agriculture is the main stay of the rural economy. It is generally known that drought is the chief cause of forced human migration and environmental refugees, deadly conflicts over the use of diminishing natural resources, food insecurity and starvation, a damage to significant habitations and as well as loss of biological diversity; volatility of socio-economic conditions, poverty, and unpredictable climatic conditions through reduced carbon sequestration possibility (Roman-Cuesta, 2007). Drought and desertification impacts are among the pricey incidents or occurrences in Africa, for instance, the prevalent destitution as well as the unstable economy of many African countries which depend on climate-sensitive segments such as rain-fed agriculture. All plants and animal life present in a particular region which are not resilient to drought are most likely to go into extinction. (Nagamuthu & Rajendram, 2015). The collective results of drought and bush burning (during dry seasons) have made the plants to go extinct and animals to drift into safer places. Drought, land degradation and desertification have had grave impacts on the richness and variety of fauna and flora (Francisco, 2013). Moreover, plants biodiversity will alter with time, unpleasant species will dominate, and total biomass production will dwindle (Khan & Gomes, 2019). Plants and animals are reliant on water, like people. Drought can minimize their food supplies and damage their habitats. Occasionally, this damage lasts for only a limited period, and other times it is irrevocable. Drought can also affect people's health and safety. For example, drought impacts on society include anxiety or depression about economic losses, conflicts due to water shortages, reduction of income, fewer recreational activities, and increase of heat stroke incidents and sometimes loss of human lives. Moreover, drought conditions can also grant a considerable increase in wildfire risk. This is due to withering of plants and trees from lack of precipitation, scourge insect infestations, and diseases, all of which are associated with drought. (Prokurat, 2015). Lengthy periods of drought can cause more wildfires and more powerful wildfires, which impinge on the economy, the environment as well as the society in a number of ways like destroying

neighbourhoods, crops and habitats (Do Amaral, Cunha, Marchezini, Lindoso, Saito, & Dos Santos Alvala, 2019). Again, drought not only always offers similar instant and remarkable visuals related with occurrences such as hurricanes and tornadoes, but it still has a huge price tag. Actually, droughts are the second in rank types of phenomena that are associated with billion-dollar weather disasters for the past three decades (Nagamuthu & Rajendram, 2015). With staggering yearly losses close to \$9 billion annually, drought is a severe hazard with socioeconomic risks for most African countries. (Siingh et al., 2011). These pricey drought impacts come in different forms. For instance, the economic impacts of drought include farmers who lose money because drought destroyed their crops or worse ranchers who may have to spend more money for animal feeds and irrigation of their crops. Economic impacts can either be direct or indirect. Directly, it could be a decrease in dairy production and indirectly, it could be observed through increases in the price of the cheese (Francisco, 2013).

MATERIALS AND METHODS

The monthly rainfall dataset of this study was obtained from National Aeronautics and Space Administration (NASA) data portal. This dataset was used as the only input parameter for Standardized Precipitation Index computation. Standardized Precipitation Index (SPI) is plainly described as a normalised index that signifies a likelihood of a rainfall occurrence of an observed rainfall amount in comparison with the rainfall climatology at a particular geographical location over a long-term reference period (Siingh et al., 2011). Furthermore, Yusof, Hui-Mean, Suhaila, Yusop, & Ching-Yee (2014) affirm that SPI is a probability index that offers an enhanced demonstration of both abnormal wetness and dryness than any Palmer indices such as Palmer Drought Severity Index (PDSI). The value of this index is that it can be computed for different time scales, for that reason, issuing early warning of drought and its severity (Gaas, 2018). This index is appropriate for risk management purposes (Verma, Verma, Yadu, & Murmu, (2016). Moreover, this index is advantageous in that precipitation is the only parameter in its computation therefore making it less complex. Conversely, the weakness of this index is that it can only compute the precipitation deficit; values founded on initial data may alter, and values vary as the period of record grows (Jordan, 2017). The table 1 below illustrates the values of SPI categorisation.

Table 1: SPI values

| SPI Value | Category | Probability % |
|---------------|----------------|---------------|
| ≥ 2.0 | Extremely wet | 2.3 |
| 1.5 to 1.99 | Very wet | 4.4 |
| 1 to 1.49 | Moderately wet | 9.2 |
| -0.99 to 0.99 | Near normal | 34.1 |
| -1.0 to -1.49 | Moderately dry | 9.2 |
| -1.5 to -1.99 | Severely dry | 4.4 |
| ≤ -2.0 | Extremely dry | 2.3 |

Source: Hlalele, 2016

The SPI calculations are founded on the fact that precipitation increases over a fixed time scale of interest, for instance; SPI-3, SPI-6, SPI-9, SPI-12, SPI-24 and SPI-48, so from that a series is integrated in a gamma probability distribution which is apt for this climatological precipitation

time series. (Yusof et al., 2014). The gamma distribution is described by the following density function.

$$g(x) = \frac{1}{\beta^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\beta} \quad \text{for } x > 0 \quad \dots\dots\dots (1)$$

Where α and β are estimated for each station as well as for each month of the year.

$$\alpha = \frac{1}{4A} \left(1 + \sqrt{1 + \frac{4A}{3}} \right) \quad \dots\dots\dots (2)$$

$$\beta = \frac{\bar{x}}{\alpha}$$

where $A = \ln(\bar{x}) - \frac{\sum \ln(x)}{n}$, and n = number of observations

After these parameters have been estimated then their resulting values are used to calculate cumulative probability as.

$$G(x) = \int_0^x g(x) dx = \frac{1}{\beta^\alpha \Gamma(\alpha)} \int_0^x x^{\alpha-1} e^{-x/\beta} dx \quad \dots\dots\dots (3)$$

In cases where $t=x/\beta$ then an incomplete gamma function becomes

$$G(x) = \frac{1}{\Gamma(\alpha)} \int_0^x t^{\alpha-1} e^{-t} dt \quad \dots\dots\dots (4)$$

Since gamma function is undefined at $x=0$ then the cumulative probability is calculated from the following equation (Rahmat, Jayasuriya, & Bhuiyan, 2012):

$$H(x) = q + (1 - q) G(x) \quad \dots\dots\dots (5)$$

where q is the probability of a zero and $G(x)$ the cumulative probability of the incomplete gamma function. If m is the number of zeros in a precipitation time series, then q can be estimated by m/n . The cumulative probability is then transformed to the standard normal random variable z with mean zero and variance one, which is the value of the SPI (Yusof et al., 2014). In the event where it is standardized, the potency of the irregularity is categorised as illustrated in Table xx, where the table also demonstrates the corresponding probabilities.

DATA QUALITY CONTROL

Homogeneity tests are carried out to scrutinize statistical properties of a certain dataset in statistics. In essence, the tests thoroughly look at the location, stability and variations which are local within the time series over time (Abraham & Yatawara, 1998). The author also confirms that this occurrence is the same as testing statistical distribution, for that reason identifying if there are any changes in the distribution. The test is also carried out to evade false or unauthentic results from the data sets. (Hosseinzadeh Talae, Kouchakzadeh, & Shifter Some'e, 2014). A non-parametric Pettitt's test was used. Outliers and missing were identified and substituted by Expectation Maximum algorithm (EIM) with the help of SPSS software. EM is described as a statistical algorithm appropriate to be used when there are missing or hidden values in the data sets (Lobato

& Velasco, 2004). Tan & Yilmaz (2002) construct that EM is a well-liked too used in statistical estimation problems that involve data which is incomplete. Likewise, Technology & Bay (2001) define EM as an algorithm that allows parameter estimation in probabilistic models with data which is not complete.

Before carrying out any data analysis, it is essential to assess the apparent proof of patterns and trends in the climate data (Kliewer & Mertins, 1997). Non-parametric Mann-Kendall test is used in the study to assess if any trends existed. This test is universally used to identify monotonic trends in series of environmental, climate and hydrological dataset. The null hypothesis (H_0) means that data came from a population with autonomous realisations is identically distributed. The alternative hypothesis (H_a) means that data follows a monotonic trend. The Mann-Kendall statistic indicates how strong and weak two variables are associated and show correlation direction (Kliewer & Mertins, 1997). One of the advantages of this statistic is that data does not necessarily have to follow any definite probability distribution. The test was conducted simultaneously with a non-parametric Pettitt's test to gauge data homogeneity and descriptive statistics.

PARAMETERS USED TO CHARACTERISE DROUGHT

The temporal characteristics are those features of a hazard associated with time and they are commonly linked with questions such as the following: When does the hazard occur? What is the frequency of the occurrence? What is the duration of the hazard? How fast do they hit and how conventional are they? (Andreadis, 2005; Van Niekerk, 2011). Drought intensity is described in numerous ways by different academics; nevertheless, According to Pope et al (2013) intensity is a degree of insufficient rainfall. The authors further explain that intensity can be defined as a result of duration as well as intensity. Abdulmaleket *al.* (2013) affirms that drought intensity gauges how far rainfall is below the average precipitation of the region. Understanding intensity can be used as a way of ascertaining the feasible impact of a hazard on communities. Understanding intensity can be used as a way of ascertaining the feasible impact of a hazard on communities as well as the levels of risk at which elements are exposed to (Van Niekerk, 2011). This aspect of drought is conveyed in several parameters such as the Standard Total Accumulative Dry Spell (STCD), Average Dry Spell Index (ADSI), Longest Multi year Drought (LMYD) and Largest Single Year Drought (LSYD) (Abdulmaleket et al., 2013). STCD signify the total cumulative drought index used. One more parameter used to quantify the same aspect is ADSI. LMYD and LSYD are other parameters obtained from drought indices such as SPI whose high values have negative outcomes on every facet of the environment, including socio-economic situation of communities. ADSI values offer valuable knowledge on the region's characteristics essential for arrangement of water resources as well as irrigation projects. Areas with low values need special attention. Likewise, The ADSI values are of great significance to decision makers for the planning of agricultural projects of the affected areas for future. The LSYD also is significant to take into consideration in crop cultivation given that crops barely survive its high values. So, these four parameters are defined by the equations below:

$$ADSI = STCD/N \dots\dots\dots (6)$$

where N=total number of years of the series

$$LMYD = \text{Maximum of any successive years} \dots\dots\dots (7)$$

LSYD = Maximum drought index value of the single year (8)

Drought Frequency and duration analysis

For a long-term planning to be effective in water projects such as irrigation and dam sizing purposes, there has to be an analysis of both dry and wet spells from a climatic and hydro-meteorological standpoint. (Abdulmalek *et al.*, 2013). In drought analysis a period declared as dry when $SPI < 0$. These are some of the parameters used to calculate the drought duration: Longest Dry Spell Duration (LDS), Drought Tendency (DT) and Average Dry Spell Duration (ADSD). LDS is described as the highest of any consecutive dry spells that occurred on one occasion through the study record N. High values of both LDS and ADSD it means that water resources planning must be considered in that particular region. Nevertheless, DT is the ratio which involves the total number of dry spell cases to the wet spell cases. This parameter measures the predisposition of the study area which suffers from the dry spells; thus it measures the frequency of a hazard under consideration. These are defined by the following equations:

$$LDS = \sum_i^N Di, i = 1, 2, \dots, N \dots\dots\dots (9)$$

$$DT = \sum D / \sum W \dots\dots\dots (10)$$

$$ADSD = \sum D / N \dots\dots\dots (11)$$

If successive dry spell cases (D) are followed by a wet spell, like D, D, D, W, D then $\sum D = 4$, and $N = 2$ since an interrupted sequence of several cases of (D) constitute only one dry spell event.

A frequency analysis offers an early warning system. Disaster managers and appropriate stakeholders have the ability to foresee when the next incident will take place. (Sobrinho *et al.* 2011). Hydro-climatic hazards such as drought have a propensity of following a seasonal pattern. When the number of times and the length of a hazard such as drought are known, such knowledge helps in planning accordingly (Hlalele, 2016). In a frequency analysis, approximation of the probability of an incidence of future occurrences is established on a primary base for risk management. (Yuliang *et al.* 2014). Again, it is used to foresee how frequently a hazard event happens over space and time (Des Jardins, 2012).

RESULTS AND DISCUSSIONS

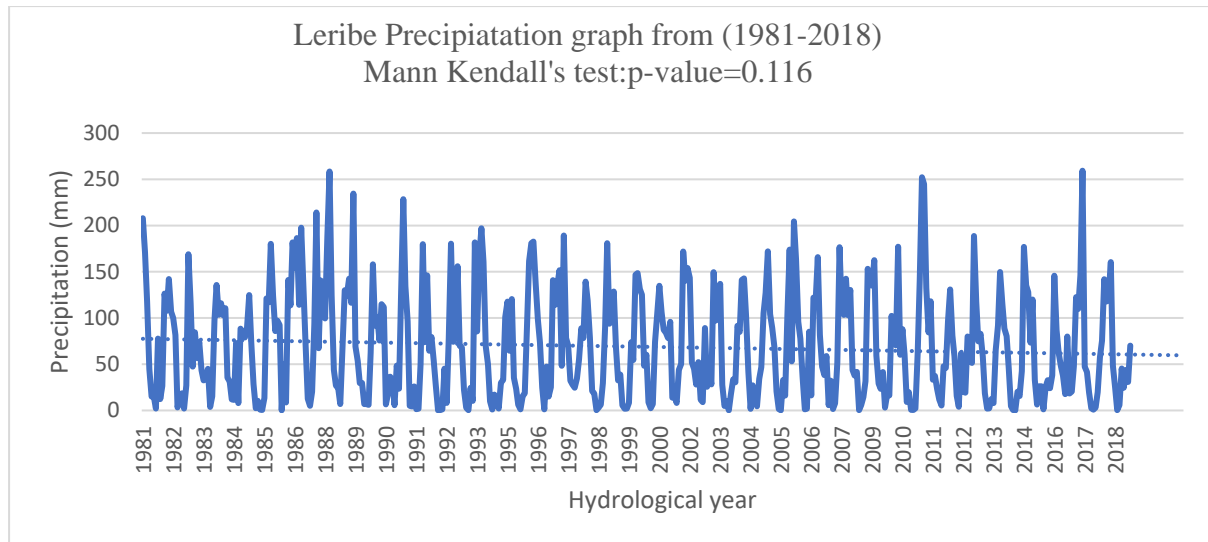

Figure 2: Leribe precipitation plot (1981-2018)

Table 2: Leribe's precipitation descriptive statistics

| Statistic | Precipitation |
|------------------------|---------------|
| Nbr. of observations | 456 |
| Nbr. of missing values | 0 |
| Minimum | 0.060 |
| Maximum | 259.290 |
| Range | 259.230 |
| 1st Quartile | 18.515 |
| Median | 54.865 |
| 3rd Quartile | 110.888 |
| Mean | 69.132 |
| Variance (n) | 3344.386 |
| Standard deviation (n) | 57.831 |

Figure 2 shows a graph of Leribe's precipitation from 1981 to 2018 where a non-parametric Mann Kendall's test indicated that there were no significant trends detected in the time series. The p-value of Mann Kendall's test was 0.116 which is greater than the significance level of 0.05. Table 2 depicts descriptive statistics where the minimum and maximum values are 0.060 and 256.29 mm respectively with a standard deviation of 57.831 mm. The average precipitation is found to be 69.132 mm. No missing values were present in the datasets, therefore there was no need for replacing them. Outliers were detected, removed and replaced by Expectation Maximum algorithm. Having explored the raw dataset, it was necessary to calculate drought index SPI on three-month time scale that corresponds to agricultural drought.

Figure 3: Leribe SPI-3 plot (1981-2018)

Figure 4: Leribe SPI-3 drought severity plot (1981-2018)

Standardised Precipitation Index (SPI-3) at three-month time scale assesses agricultural drought. Figures 3 and 4 show both the graphs of SPI-3 and its drought severity from 1981 to 2018. The SPI-3 showed a statistically decreasing trend. A decrease in SPI-3 implies an increase in drought intensity. The severity plot shows that study area under constant frequent drought severity on SPI-3 where the 1992/3 and 2015/16 are seen to have had to most severe drought events. These are the years in which drought was declared a disaster in the country and the neighbouring country, South Africa in 2015/16. Several drought parameters were then extracted from the SPI-3 to provide a holistic view of the study area in terms of drought conditions. Table 3 shows drought parameters to characterise drought on SPI-3 scale. It can be seen that dry spells events (D) are approximately equal to wet spells (W). The study area had 52 drought events with an average dry spell duration (ADSD) of 4.21 months. A drought tendency of 0.93 shows how frequently SPI-3 droughts are in the study area. Drought is said to be extreme if SPI value reaches -2 and below, therefore the study area receives an average of -3.44 drought intensity every 4 months, as shown by ADSD.

Table 3: Drought parameters

| LSDS | D | W | DT | N | ADSD | STCD | ADSI | LYSYD |
|--------|-----|-----|------|----|------|--------|-------|-------|
| -19.23 | 219 | 235 | 0.93 | 52 | 4.21 | -179.0 | -3.44 | -2.97 |

An exploratory factor analysis was applied to the computed SPI-3 to cluster similar months in groups. An greater than 1 eigenvalue rule was applied to get factors that belonged to similar groups. A cluster based rotation was applied over all the thelve. Table 4 shows the cluster rotated matrix with loading on each month. The researcher selected loadings above 0.300 as highlighted in the table 4. This is where months were loaded in different groupings as it would be expected from known seasons. January formed a factor on its own implying a change in a season where January belonged. Spring was found to be longer than normal as shown while winter season was fragmented in which case February part. Table 5 shows a criterion used to judge factors in table 4, where a non-significant chi-square with p-value =0.915 was found

Table 4: Factor Loadings

| | Factor 1 | Factor 2 | Factor 3 | Factor 4 | Uniqueness |
|-----|----------|----------|----------|----------|------------|
| APR | 0.457 | 0.233 | 0.065 | 0.134 | 0.664 |
| AUG | 0.109 | 0.428 | 0.069 | -0.033 | 0.798 |
| DEC | -0.224 | 0.351 | 0.105 | 0.047 | 0.846 |
| FEB | 0.172 | 0.058 | 0.209 | -0.399 | 0.793 |
| JAN | 0.027 | -0.031 | 0.992 | -0.075 | 0.004 |
| JUL | 0.269 | -0.206 | -0.005 | 0.545 | 0.562 |
| JUN | -0.031 | 0.143 | 0.059 | 0.449 | 0.772 |
| MAR | 0.783 | -0.012 | -0.089 | -0.117 | 0.412 |
| MAY | 0.422 | -0.241 | 0.063 | 0.030 | 0.768 |
| NOV | -0.025 | 0.300 | -0.153 | -0.200 | 0.836 |
| OCT | -0.129 | 0.502 | -0.042 | 0.047 | 0.735 |
| SEP | 0.241 | 0.599 | -0.042 | 0.022 | 0.542 |

Note. Applied rotation method is cluster.

Table 5: Chi-squared Test

| | Value | df | p |
|-------|--------|----|-------|
| Model | 15.179 | 24 | 0.915 |

Having determined these factors, a confirmatory factor analysis was conducted to confirm that indeed these months belonged to the groupings as determined by the cluster based rotation exploratory factor analysis. The confirmatory analysis confirmed the factor belongings. Table 6 shows the model fit judged by chi-square with a p-value of 0.692. Chi-sqaure is sensitive to sample size, therefore further indices were used to assist the judgement of the model fit. From table 7 and 8 all the selected fit indices were within the expected ranges to render the model suitable. Both Comparative Fit Index (CFI) and Tucker-Lewis Index (TLI) values must be above 0.9 for the model to be said good. These indices were then 1 and 0.981 respectively. A third index Root mean square error of approximation (RMSEA) was used. This index must be <0.05 to be rendered good. Therefore, its value was found to 0.000 as shown from Table 7.

Table 6: Model fit, Chi-square test

| | X ² | df | p |
|----------------|----------------|----|-------|
| Baseline model | 14.870 | 10 | 0.915 |
| Factor model | 3.051 | 5 | 0.692 |

Table 7: Additional fit measures

| Index | Value |
|--|-------|
| Comparative Fit Index (CFI) | 1.000 |
| Tucker-Lewis Index (TLI) | 0.981 |
| Bentler-Bonett Non-normed Fit Index (NNFI) | 1.801 |
| Bentler-Bonett Normed Fit Index (NFI) | 0.795 |
| Parsimony Normed Fit Index (PNFI) | 0.397 |
| Bollen's Relative Fit Index (RFI) | 0.590 |
| Bollen's Incremental Fit Index (IFI) | 1.198 |
| Relative Noncentrality Index (RNI) | 1.400 |
| Comparative Fit Index (CFI) | 0.981 |

Table 8: Other fit measures

| Metric | Value |
|---|---------|
| Root mean square error of approximation (RMSEA) | 0.000 |
| RMSEA 90% CI lower bound | 0.000 |
| RMSEA 90% CI upper bound | 0.172 |
| RMSEA p-value | 0.734 |
| Standardized root mean square residual (SRMR) | 0.058 |
| Hoelter's critical N ($\alpha = .05$) | 138.899 |
| Hoelter's critical N ($\alpha = .01$) | 188.922 |
| Goodness of fit index (GFI) | 0.995 |
| McDonald fit index (MFI) | 1.026 |
| Expected cross validation index (ECVI) | 0.870 |

CONCLUSION AND RECOMMENDATIONS

In conclusion, scientists have warned that there will be changes in the climate hence resulting frequent extremities such as floods and drought events. Seasons would be longer and highly variable. These variations are likely to adversely impact on environmental and socio-economic systems. A non-parametric Mann Kendall's test was used for monotonic trends patterns detection over the precipitation time series, where there was no trend in the entire series but a statistically decreasing trend in SPI-3 with a p-value = 0.00013. Exploratory factor analysis was employed to cluster months into new seasons. Four factors were extracted using a greater than 1 eigenvalue rule, with a chi-square p-value=0.915. The new seasons depicting new seasons were subjected to a confirmatory factor analysis where model fit indices; Comparative Fit (CFI), Tucker-Lewis (TLI) and Root Mean Square Error of approximation (RMSEA) indices were all within expected thresholds levels. The cluster-based rotation revealed new seasons where Spring was found to be longer and extended into Summer, a shorter Autumn and fragmented Winter season all with severe drought episodes. The study then recommends a paradigm shift in crops growing times and cultivators to cash crops that are drought resistant.

THE DEVELOPMENT OF THE SOUTH AFRICAN CREDIT DERIVATIVE MARKET DURING ITS FIRST DECADE

S. Kennedy-Palmer

University of South Africa, Pretoria, South Africa

ABSTRACT

The South African over-the-counter credit derivatives market is a potential source of systemic risk contagion. Opacity in some credit derivative markets was at the core of the 2008/09 global financial crisis, prompting new regulations designed to give authorities access to information on the size and composition of this market for macro-prudential supervision. This article analyses the evolution of the size and composition of this market from 2005 to 2016 using data from the South African Reserve Bank (SARB). The study found that despite the initial slump after the crisis, the market has witnessed a significant increase with the notional amounts outstanding reaching R133bn in January 2016 (adjusted for inflation, using 2005 as the base year) up from only R32bn in January 2005. The enforcement of a capital charge on non-centrally traded OTC derivatives in early 2015 could have had an unintended positive effect on the size of the credit derivatives market because banks are permitted to hedge against this charge using credit derivatives. As the regulatory environment continues to change, policymakers should be aware of the unintended consequences of regulation on the credit derivatives market as this market allows for large leveraged exposures to credit risk.

Keywords: Credit derivatives, South Africa, global financial crisis 2008/2009, capital requirements, credit valuation adjustment

1. INTRODUCTION

1.1 Statement of the research problem

Credit derivatives exacerbated losses during the global financial crisis of 2008/09, leading to the failure of some systemically important financial institutions, jeopardizing the stability of the global financial system (Blanchard, 2009). Credit derivatives are unique amongst all asset classes of derivatives because they expose the protection seller to an asymmetric jump to default risk. Prior to the crisis, all credit derivatives were traded over-the-counter (OTC) through dealers with almost no direct supervision despite the large size of this market (National Treasury, 2012). Commercial banks were the only market participants legally required to report on the notional amounts of their outstanding derivatives prior to the crisis, whilst investment banks and insurers (such as Lehman Brothers and AIG respectively) were not. It was this opacity of the OTC derivatives market which created uncertainty about the exposure of some systemically important financial institutions through their credit derivatives positions (Stulz, 2009: 58–70), exacerbating counterparty credit risk (CCR).

A survey prepared by the International Swaps and Derivatives Association (ISDA, 2010) showed that the global market size for credit default swaps (one type of credit derivative) more than doubled in size each year from a notional value of US \$3.7tn in 2003 to \$62.2tn at the end of 2007.

The notional value of credit default swaps (CDSs) exceeded the global gross domestic product (GDP) in 2007, which was only US \$57.5tn (The World Bank, 2016). Muyambiri & Odhiambo (2018) find that financial development has an empirically significant impact on investment in individual countries. The South African OTC derivatives market is large in relation to the country's economy (International Monetary Fund [IMF], 2015); and it is the only derivatives market in Sub-Saharan Africa (Adelegan, 2009). The big five South African banks are the primary market makers in the country, therefore systemic risk in the derivatives market could spill over into the larger financial system as it did during the financial crisis. The World Bank considers total bank assets to GDP as a good measure of the depth of a country's financial system. Total bank assets as at December 2015 was R4.8 trillion (SARB, 2015) whilst GDP for 2015 is estimated at 4.5 trillion ZAR. Therefore, South African banks' balance sheets make up a large portion of the country's economy. Thus, information on the size and composition of the South African market is necessary for academics and regulators alike to assess the possible impacts of regulatory changes to this important financial market. A trade repository is valuable for reducing systemic risk because it aggregates and stores important data on transactions, which can be accessed by authorities for macro-prudential supervision as well as during a financial crisis to assess CCR, thereby reducing the opacity of the market for these complicated instruments (National Treasury, 2012).

According to a former South African credit derivatives trader,¹ the local market is characterized by a handful of local banks acting as market makers with very little local interbank trade. Trade between local banks and foreign dealers tends to be largely one-directional; where South African banks buy protection from local nonbank institutional clients, and in turn, foreign dealers buy protection from local banks, primarily to hedge against South African based risks. The IMF confirmed this market structure, indicating that interbank trading between South African and offshore banks constitutes a significant part of transactions in the OTC derivative market and that "domestic banks use foreign dealers primarily to offset risk exposures assumed from domestic nonbank financial institutions" (IMF, 2015: 12) This means that most transactions will have one of the local reporting banks as a counterparty with very few instances of double counting, i.e. where both counterparties are reporting banks, meaning that aggregate values are a good approximation of market size.

To date (April 2022), a trade repository has not been licenced and central clearing and trading have not yet been mandated nor has the market been subject to trade compression, therefore the market can only be analysed on an aggregate basis. Thus, given the lack of central clearing and trade compression for the South African CDS market as well as the one-directional transfer of risk with domestic banks acting as dealers, one can infer that the notional amounts outstanding presented in this article provide a relevant and useful estimation of market size. Given the relative size and regional importance of this market, this paper seeks to provide possible explanations for changes to the size and composition of this market from its infancy in 2005 to 2016, before the implementation of any post-crisis reforms excluding CVA in 2015, shedding light on this otherwise opaque market.

¹ *Acknowledgement:* Special thanks for the insights and contributions from a former South African credit derivatives trader who wishes to remain anonymous.

1.2 Study Objectives

Given the relative size and regional importance of this market, this paper seeks to provide possible explanations for changes to the size and composition of this market from its infancy in 2005 to 2016. Devoid of a local trade repository to date, information about the size and the composition of the South African OTC derivatives market is limited to the information which commercial banks report to the South African Reserve Bank (SARB) on a monthly basis in the BA350 form (National Treasury, 2012).

This study analyses and evaluate the size and composition of the South African OTC credit derivatives market from 2005 to 2016 using data aggregated by the SARB, increasing transparency in this otherwise opaque market. This study further conducts an examination of the variances in the size of the credit derivatives market as an absolute value and relative to the total of all other OTC derivatives annually over the period January 2005 to January 2016.

2. LITERATURE REVIEW

Credit derivatives are financial instruments that allow parties to transfer credit risk (Choudhry, 2012). CDSs transfer the risk of a credit event involving the underlying reference entity, such as bankruptcy or default from the protection buyer to the protection seller; thus, providing a method for hedging credit risk (Choudhry, 2012). However, CDS protection buyers do not need to have an interest in the underlying reference entity; therefore, they can be used for purely speculative purposes. Credit derivatives require a small initial outlay when they are created; therefore, they can be highly leveraged to create large outstanding notional values. Moreover, unlike most other derivative products, CDSs have a highly asymmetric distribution of risk between counterparties because the protection seller faces much higher potential losses than the protection buyer.

Nijskens and Wagner (2011) found that the ability to transfer credit risk reduced individual banks' volatility prior to the crisis; however, credit risk transfer resulted in higher levels of systemic risk in the financial system. Credit derivatives were found to amplify systemic risk during the crisis via direct losses as defaults triggered embedded derivatives as well as indirect mark-to-market losses through increased CCR (Nijskens and Wagner, 2011). On 15 September 2008 Lehman Brothers filed for bankruptcy after suffering large losses on mortgage-backed securities. CCR soared in the wake of this news as Lehman Brothers had more than \$600bn in assets of which it was unclear how much was owed to other financial institutions due to the opacity of the OTC derivatives market (Blanchard et al., 2014). At the cash settlement auction for CDSs on Lehman Brothers debt on 10 October 2008, the recovery rate was set at 8.625 percent. That meant that protection sellers had to pay out 91.375 percent of the notional amount outstanding of CDSs where Lehman Brothers debt was the reference entity (Stulz, 2010). Although the demise of Lehman Brothers was not due to credit derivatives, the resulting increases in CCR amplified systemic risks and led to mark-to-market losses on many asset classes.

CCR is the risk that the counterparty to a transaction defaults before the transaction is settled, thus it is the two-way risk between the two parties to a contract that the counterparty will default (Gregory, 2010). As the 2008/09 crisis unfolded, CCR increased as general market risk factors increased and this positive correlation is known as wrong-way risk (Canabarro and Duffie, 2003). Defaults and mark-to-market losses increased CCR, which pro-cyclically resulted in further mark-to-market losses (EU Commission services, 2010). Higher CCR required more collateral to be

posted to counterparties further constraining liquidity, and the ensuing liquidity crisis threatened the operation of otherwise solvent institutions (Blanchard, 2009). In fact, the Basel Committee on Banking Supervision (BCBS) noted that approximately two-thirds of CCR losses were due to mark-to-market losses and only one third due to actual defaults (Bank for International Settlements [BIS], 2009). The US Federal Reserve was quick to respond, supplying liquidity to the market. The Bank of England and other central banks followed suit preventing what could arguably have been a catastrophic disintegration of the global financial system.

In response to the information asymmetry in the OTC derivatives market, the G20 issued a directive in 2009 to improve the transparency of this market through the establishment of trade repositories as well as the central clearing and/or central trading of appropriate derivatives, while non-centrally cleared derivatives would be subject to higher capital requirements in the form of a credit valuation adjustment and a debt valuation adjustment. In November 2011, the Group of 20 (G20) leaders further agreed to add margin requirements for non-centrally cleared OTC derivatives (National Treasury, 2015). South African banks have had to maintain full capital requirements for credit valuation adjustment (CVA) risk since 1 April 2015 (SARB, 2015), and the margin requirements for non-centrally cleared derivatives begun to be phased in during 2019. To date, a trade repository has not been licenced and central clearing and trading have not yet been mandated nor has the market been subject to trade compression. Vause (2010) found that in the first half of 2010 gross notional amounts outstanding for the global CDS market was almost half that of its size at end 2007. He found that this shirking in notionals was not due to decreased trading in the market, in fact, trading volumes had grown strongly in the period. Rather, Vause found that the lower notional amounts outstanding were due to efforts to reduce CCR such as trade compression and central clearing

South African financial markets remained robust during the crisis, however, stunted global economic activity negatively affected local growth. South Africa's average growth rate between 2000 and 2007 was 4.3 percent, but this declined to 3.8 percent in 2008 and down to -1.5 percent in 2009 (Blanchard et al., 2014). The South African stock market fell by 36.0 percent between May and December 2008, and almost one million jobs were lost (Financial Stability Board, 2013). According to the Financial Stability Board, South Africa was one of the worst affected emerging economies, thus international regulatory reform designed to dampen the effect of future financial contagions has benefits for the local market. As a member of the G20, South Africa has committed to implement OTC derivative market reforms in line with other G20 nations to avoid international regulatory arbitrage (National Treasury, 2012).

3. METHODOLOGY

Reporting guidelines for the 2016 Triennial Central Bank Survey issued by the BIS advise that the two best measures of the size of the OTC derivatives market are data on notional amounts outstanding and gross market values (BIS, 2015b). According to the BIS:

“Notional amounts outstanding are comparable to measures of market size in related underlying cash markets and shed useful light on the relative size and growth of cash and derivatives markets... gross market values at current market prices provide a measure of derivatives market size and economic significance that is readily comparable across markets and products (BIS, 2015b: 4-5).”

A single comprehensive measure of risk does not exist; however, the BIS uses the concept *market value* (BIS, 2015b: 1) whereas the SARB uses the concept *fair value* (SARB, 2012: 666). Market value is the cost of replacing all open contracts at prevailing market prices. Conversely, the SARB regards fair value as a broader term than market value since the market value of an instrument refers to the price obtainable in an active market. According to the IMF, “The measurement of fair values maximizes the use of relevant and reliable inputs and [is] consistently applied for risk management and reporting purposes” (IMF, 2015: 70). Even though there is no single complete measure of market risk, the concept of fair value is used by the SARB to identify potential losses. The data for this article is sourced from the SARB and thus this article reports on fair value. The SARB mandates that all commercial banks complete and submit the BA350 form monthly (The OTC Derivatives Working Group, 2012: 32-33). The content of the individual forms submitted by banks is confidential and not available for public review; however, the SARB publishes (on its website) the accumulated data for the South African banking sector. The consolidated data distinguish between transactions entered into through a formal exchange and those entered into OTC in respect of the following derivative categories: interest rate, foreign exchange, credit, equity and commodity instruments (SARB, 2012: 659-663).

The notional amounts outstanding presented in this analysis could be overstated for a variety of reasons but all these factors are partly, if not largely, offset. One can thus infer that the notional amounts outstanding provided in this analysis give a relevant and useful estimation of the size of real market year on year (YoY) growth from January 2005 to January 2016.

The first factor that could lead to overstated notional amounts is agreements where counterparties are also reporting banks as opposed to another financial institution or non-financial customers; thus, the contract is counted twice (BIS, 2015b). Double counting is not a significant factor in the South African credit derivatives market because the local inter-dealer market is limited and reporting banks rarely transact with each other (Anonymous, 2016).

The second factor leading to the possible overstating of notional amounts outstanding is the difficulty in unwinding CDSs. Instead of cancelling or unwinding CDSs, the party would normally buy a corresponding CDS to offset the initial exposure. However, after ISDA’s Big Bang protocol in 2009, scheduled termination dates of CDSs must always match a quarterly roll date. These quarterly roll dates are always 20 March, 20 June, 20 September and 20 December. On these dates, dealers are able to collapse their books, that is, netting protection bought and sold for each of their counterparties. The South African market is characterized by limited inter-dealer trading by local dealers, and a largely one-directional transfer of risk in trades with foreign dealers, so the benefits of portfolio compression would be limited.

Since the crisis, technology companies have been offering portfolio compression services whereby redundant CDSs are eliminated. An example is triReduce from TriOptima, originally a Swedish company with global offices. According to the company, by 2009, redundant CDSs with a notional outstanding amount of \$60.2tn were eliminated (National Treasury, 2012). However, portfolio compression such as triReduce has not yet been applied to the credit derivatives market in South Africa². As is the case with bilateral netting made possible by standardized termination dates, the

² Portfolio compression has been applied to South African rand (ZAR) interest rate swaps. On 6 October 2014, TriOptima announced that after its first triReduce compression cycle for cleared South African rand (ZAR)

effect of portfolio compression would arguably be minimal because of the largely one-directional transfer of risk that characterizes the South African credit derivatives market with limited local inter-dealer activity. Thus, trade compression is not a limitation in the interpretation of the South African market size.

3.1. Methods: Indicators and computations

3.1.1 Total notional amounts outstanding and computations

The notional amount outstanding of a derivative is defined as the nominal amount underlying the respective derivative contract (BIS, 2015b), i.e. the contracted base value on which payments and receivables are calculated (SARB, 2012). Notional amounts outstanding also provide useful information on the structure of the OTC derivatives market as well as being a rough estimate for the potential transfer of price risk in derivatives markets (BIS, 2015b). However, because notional amounts outstanding represent the potential transfer of price risk, they should not be interpreted as a measure of the riskiness of these positions.

For the research on which this article reports, the notional amounts outstanding annually at month-end for January 2005 to January 2016 were calculated for credit derivatives in accordance with the method used by the BIS and the ISDA and the OCC, as per the following methodology:

$$\text{Total notional amounts outstanding} = \text{protection bought} + \text{protection sold}$$

Equation 1: Computation of total notional amounts outstanding.

Totals for banking book and trading book activities were added. The distinction between banking book and trading book activities is primarily based on the subjective intention of the individual bank. Assets which the bank intends to keep until maturity for hedging purposes are listed in the banking book, while those assets the bank intends to trade are listed under the trading book (BIS, 2013).

The data were analyzed on a year-on-year basis using January as the reference month. The GDP deflator was used to adjust for inflation and all amounts are therefore reported in constant (real) prices, with 2005 as the base year. The GDP deflator is defined as the ratio of the nominal estimates of GDP to the real estimates of GDP (Stats SA, 2012). As data for the same month (January) of each year was analysed, seasonal fluctuations were not a concern.

3.1.2 Gross fair values and computations

Gross negative fair value refers to the accumulated fair value of contracts where the reporting bank owes money to its counterparties, without taking into account netting or collateral. This represents the maximum losses the bank's counterparties would incur from the bank's default assuming there is no netting of contracts, and no bank collateral is held by its counterparties (OCC, 2014). The figures for negative fair value are reported as absolute amounts. Conversely, the gross positive fair value reflects the values of contracts where the reporting bank would lose money if its counterparties defaulted, without taking into account netting or collateral (SARB, 2012). When a

interest rate swaps had been completed, and \$284.3bn in notional amounts outstanding had been eliminated for LCH.Clearnet's SwapClear members.

derivative has a positive fair value the reporting bank is said to be in the money and when it has a negative fair value the reporting bank is out of the money (van Wyk, Botha, and Goodspeed, 2015).

Prior to the financial crisis, Basel II required banks to hold capital against the risk of counterparty default on their OTC derivatives portfolio; however, potential mark-to-market losses from credit valuation adjustments were not capitalized. In response to CCR losses during the crisis, Basel III introduced a (CVA - the adjustment to the fair value of derivatives to account for CCR) variability charge into the pricing of derivatives (BIS, 2015a). Debt valuation adjustment (DVA), on the other hand, refers to the losses of the reporting bank's counterparty if the reporting bank defaults. CVA is thus the market value of CCR and is a cost to the reporting bank as it reduces the positive fair value of derivatives that are assets for the bank (BIS, 2015a). DVA conversely reduces the negative fair value of derivatives that are liabilities for the bank. Banks are permitted to use CDSs to reduce their exposure to CVA, which could result in a disproportionate increase in the market size of credit derivatives compared to the OTC derivatives market as a whole especially in established markets (Anonymous, 2016).

The original framework for calculating CVA was based on the probability of default of one counterparty only; however, the BCBS issued a revised framework in 2015 for comment. The new framework includes a CVA charge for underlying market risk factors, i.e. mark-to-market adjustments (BIS, 2015a). According to Van Vuuren and Esterhuysen (2014), proposed methodologies for calculating CVA were found to be “unstable and unreliable at high average spread levels” thus requiring stronger mathematical models to avoid instability and unintended consequences in volatile times. CVA is deducted from the fair value of derivatives where the reporting bank is in the money, i.e. it reduces positive fair value of derivatives recorded as an asset. Conversely, DVA is deducted from the fair value of derivatives where the bank is out of the money, i.e. it reduces the negative fair value of derivatives recorded as a liability.

The BIS calculates gross market value by adding the absolute values of all open contracts with either positive or negative mark-to-market value, before counterparty or any other netting (BIS, 2015b). Thus, in the present research, gross fair value is calculated as follows:

$$\text{Gross fair value} = \text{absolute gross positive fair value} + \text{absolute gross negative fair value}$$

Equation 2: Computation of gross fair value.

With the implementation of Basel II, banks have been required to complete and submit the BA series of forms to the SARB. However, prior to 1 January 2008, banks would complete and submit the DI series of forms. The BA350 and DI430 forms are largely equivalent and record the derivative positions of reporting banks on a monthly basis. Both were used to calculate notional amounts outstanding, however, it was not possible to extract gross fair value for credit derivatives using the DI430 form. Thus, it is not possible to report on gross fair value for January 2005, 2006 and 2007.

4. RESULTS AND DISCUSSION

Notional amounts outstanding and gross fair value were reported on a year on year (YoY) basis to indicate the development of the size of the South African credit derivatives market between 2005 and 2016.

4.1. Notional amounts outstanding

In Figure 1, notional amounts outstanding for credit derivatives where the reporting bank was a protection buyer and a protection seller are illustrated.

Figure 1: Notional amounts outstanding for credit derivatives: protection buyer versus protection seller

Source: Compiled by researcher using data obtained from the SARB (2016)

A 31 percent drop in the notional amounts outstanding for credit derivatives (see Figure 1) was recorded YoY from January 2005 to January 2006, while January 2006 to January 2009 saw a prolonged period of YoY growth with market size at January 2009 triple the January 2006 figure. On 21 February 2007, the Minister of Finance announced exchange control reforms that removed several barriers to growth in the market for derivatives in all asset classes (Adelegan, 2009). This period saw an increase in instruments available to institutional clients. For instance, in 2008, Absa introduced new products such as enhanced return credit-linked notes (CLNs) and inflation credit-linked notes, and this period also saw an increase in the number of market participants (*Risk*, 2008). This is a possible factor for the YoY growth seen from January 2007 to January 2008. According to a former South African credit derivatives trader, after Lehman Brothers filed for bankruptcy on 15 September 2008, market activity was muted from that time until January 2009 (Anonymous, 2016). Therefore, the YoY growth seen from January 2008 to January 2009 would have been mostly from February 2008 until mid-September 2008. The YoY market size then dropped 13 percent from January 2009 to January 2010. This could have been the result of lower market confidence after the crisis. The Big Bang protocol was adhered to in April 2009, and dealers ‘collapsing’ their books would have reduced the YoY notional amounts outstanding from January 2009 to 2010 however the limited local inter-dealer market and largely one-directional risk transfer from foreign banks to local banks would limit the effect on notional amounts outstanding. It can be deduced that the fall in notional values was primarily due to the financial crisis. Market size

was on an upward YoY trend from January 2011 until January 2015, spiking in January 2016 at R133bn.

Compared with January 2015, the YoY spike in January 2016 of 38 percent may have in some way resulted from the enforcement of the CVA charge on non-centrally cleared derivatives. The SARB directed banks to maintain the full capital requirements for CVA risk from 1 April 2015 (SARB, 2015), up until then they had been largely exempted. Banks are permitted to hedge their CVA risk using CDSs; therefore, the regulation could have had an inadvertent positive effect on the size of the credit derivatives market. However, a former credit derivatives trader, cautions that the South African credit derivatives market is developing and lacks the depth and liquidity to benefit properly from the incentive created by CVA to use CDSs (Anonymous, 2016). If the local market is in fact not in a position make use of CDSs to hedge CVA risk then the large spike in 2016 is unexplained. It is possible that some market forces are driving this growth, however, it could also be an anomaly resulting from reporting errors.

During the observation period (January 2005 – January 2016), protection sold by banks generally balanced protection bought by banks, the exceptions being January 2011 and January 2012, when protection sold dwarfed protection bought. During the same period (January 2011 – January 2012), the size of other credit derivatives reported for protection bought plummeted, falling by nearly 70 percent from R29bn in January 2010 to R8bn in January 2011. January 2012 remained low at R9bn before notional amounts outstanding started picking up again in January 2013. It is therefore possible that this large anomaly is due to reporting errors, and that the credit derivatives books of South African banks were more balanced than the YoY notional amounts outstanding for January 2011 and 2012 indicate. In Figure 2, the notional amounts outstanding for credit derivatives are expressed as a percentage of the notional amounts outstanding for all other derivative asset classes.

Figure 2: Size of the total credit derivatives market compared to the rest of the OTC derivatives market

Source: Compiled by researcher using data obtained from the SARB (2016)

The YoY size of the credit derivatives market as a percentage of the size of the rest of the OTC derivatives market in South Africa remained between 0.3 percent and 0.4 percent from January 2006 to January 2012, with only January 2005 and January 2007 breaching the 0.4 percent mark. However, during January 2013, 2014 and 2015, the size of the credit derivatives market was over 0.5 percent of the rest of the OTC market. The credit derivatives market did grow by 30 percent YoY from January 2012 to January 2013, which partly explains this jump. Another possible contributor could be the use of portfolio compression for interest rate swaps. On 6 October 2014, TriOptima announced that after its first triReduce compression cycle for cleared South African rand, interest rate swaps had been completed, \$284.3bn in notional amounts outstanding had been eliminated for LCH.Clearnet's SwapClear members. This decline in notional amounts outstanding for interest rate swaps could have raised the size of the credit derivatives market as a percentage of the size of the rest of the OTC derivative market artificially.

January 2016 saw a 38 percent YoY increase compared to January 2015. This large increase in the relative size of the credit derivatives market could have been partly explained by the enforcement of CVA charges on non-centrally cleared OTC derivatives from 1 April 2015. The size of the total market for OTC derivatives shrunk slightly YoY in January 2016 compared to January 2015, which could also have been due partly to the enforcement of the CVA charge. Local dealer banks transact with foreign dealers who are primarily located in the European Union, where a full CVA charge is not yet mandatory. This could put local banks at a disadvantage when entering into contracts with European banks. CVA could thus have had a distortive effect on the sizes of both the total OTC and the credit derivatives market leading to a large increase in the relative size of the credit derivatives market as a percentage of the total OTC derivatives market.

4.2 The composition of the SA credit derivatives market 2005-2016

The BA350 form classifies credit derivative instruments into three subcategories for reporting purposes, namely CDSs, total return swaps (TRSs) and 'other' which include CLNs. CDSs transfer the risk of a credit event involving the underlying reference entity. TRSs transfer the cash flows from the underlying reference entity (such as a loan or a bond) in return for interest payments, thereby hedging interest rate receipts for one party while the other accepts the risk of variable returns (Choudhry, 2012: 30). CLNs are similar to CDSs, but they differ in one crucial respect, namely, they are funded, while hardly any CDSs are funded in practice (Choudhry, 2012: 22). The CLN issuer is the protection buyer and the CLN investor is the protection seller. Investors buy securities from the CLN issuer usually through a special purpose vehicle (SPV). A SPV is a separate legal entity, sometimes known as off-balance-sheet entities, which allow banks to move assets and liabilities off their balance sheets (Blanchard et al., 2014). The CLN buyers receive fixed or floating coupon payments for the life of the security and at maturity and, as long as there has not been a credit event, they receive par value. If the reference entity experiences a credit event, the CLN issuer will pay the investors only the recovery rate (Choudhry, 2012). The SPV enters into a CDS selling protection against the default of the reference entity. A CLN, therefore, has an embedded CDS.

4.2.1 Market composition where local banks are protection buyers

Figure 3 below illustrates the composition of the market for credit derivatives per instrument where the reporting bank is a protection buyer.

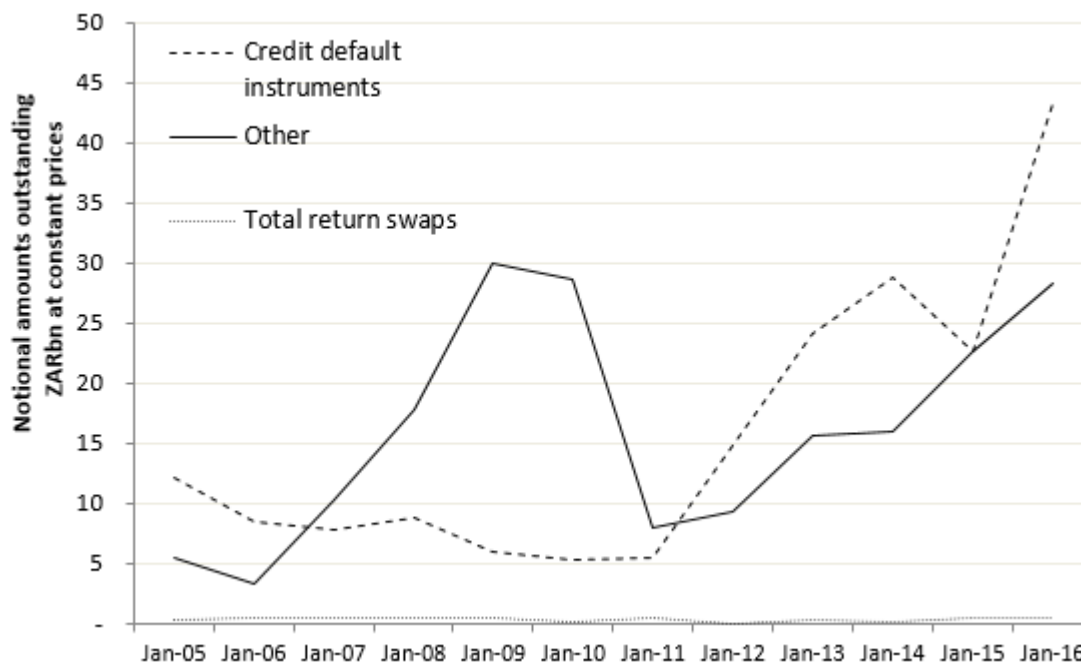

Figure 3: Notional amounts outstanding for credit derivatives per instrument where the reporting bank is a protection buyer

Source: Compiled by researcher using data obtained from the SARB (2016)

If one examines the development of the size of the CDS market where the reporting bank is a protection buyer depicted in Figure 3, the observed results can be separated into six distinct periods. The first period includes only January 2005, for which the notional amount outstanding was over R10bn. The second period sees a 31 percent YoY drop in notional amounts outstanding beginning in January 2006 and continuing until January 2008, where notional amounts remained at around R8bn. The third period sees a further YoY drop in notional amounts outstanding, starting in January 2009 until January 2011 where they remained just above R5bn. This third period could be in reaction to the global financial crisis, resulting in a decline in desirability of these instruments. The fourth period sees a rapid increase in the YoY growth rate of notional amounts outstanding for CDSs, starting in January 2012 and continuing until January 2014. YoY notional amounts almost tripled between January 2011 and 2012 and saw a further 63 percent increase from January 2012 to 2013. Growth then tapered with the YoY period from January 2013 to January 2014 seeing only a 19 percent increase. The fifth period, i.e. only January 2015, sees a decline in the notional amounts outstanding to R23bn, down from R29bn in January 2014. The sixth period sees a large increase with notional amounts outstanding almost doubling to R43bn in January 2016. The TRSs market size recorded insignificant amounts when compared with the whole credit derivatives market over the observed period, and will therefore not be discussed in further detail.

The development of the size of ‘other’ credit derivative instruments over the observed period has fluctuated greatly. There is a healthy market for CLNs in South Africa. South African banks issue and sell CLNs to other local market participants to offset the protection they have sold to foreign banks. The observed period can be separated into three distinct periods. The first period spans January 2005 to January 2006, which saw a YoY decline of 38 percent in the notional amounts outstanding of other credit derivatives. The second period started in January 2007 and ended in January 2010. Market size almost triples from January 2006 to 2007 and increased by a further 74

percent and 67 percent in January 2008 and 2009 respectively before tapering off to R29bn in January 2010. The size of the market dropped drastically YoY between January 2010 and January 2011, falling by 72 percent to R8bn from R29bn. The third period then saw another period of continuous growth in the market size, ranging from January 2011 to January 2016 reaching R28bn in January 2016. Reporting errors could be responsible for the vast fluctuation in ‘other’ credit derivatives where some banks reported CLNs a. Ag. s credit derivatives for protection bought and others did not (Anonymous, 2016).

4.2.2 Market composition where local banks are protection sellers

The size of the market for credit derivatives for all instruments differs significantly where the bank is a protection seller compared to a protection buyer. South African banks primarily sell protection to foreign banks, with CDSs the instrument of choice (see Figure 4).

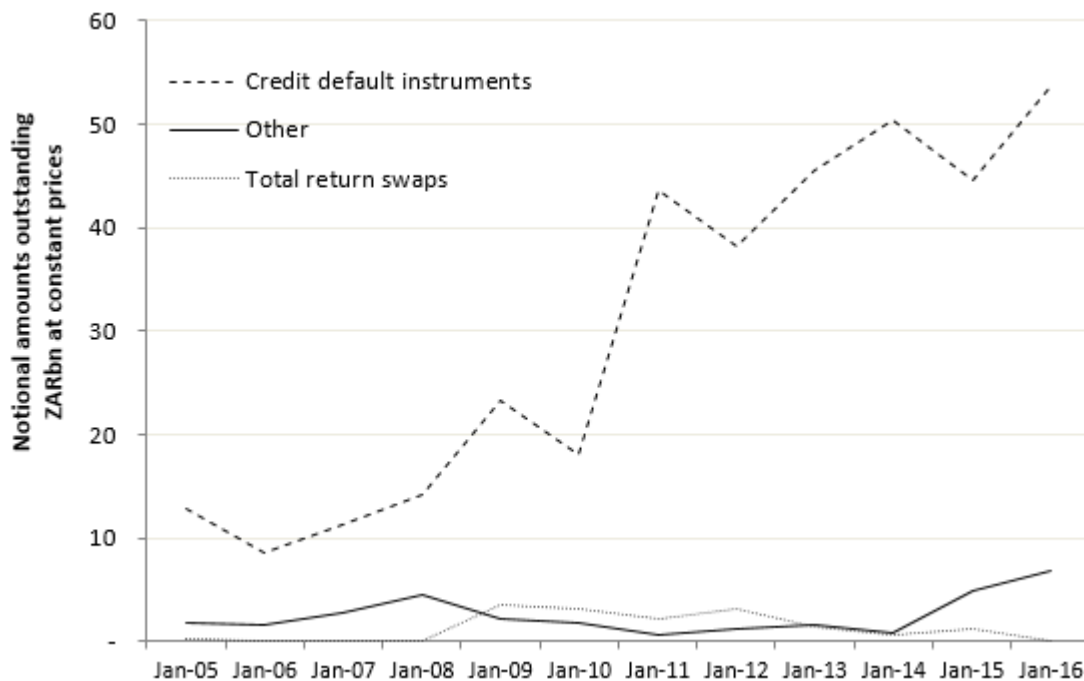

Figure 4: Notional amounts outstanding for credit derivatives per instrument where the reporting bank is a protection seller

Source: Compiled by researcher using data obtained from the SARB (2016)

For CDSs, the market size followed a generally increasing trend over the observable period (i.e. January 2005 – January 2016). However, there were few instances of annual declines in market size observed. The first of these declines was 33 percent YoY from R13bn in January 2005, to R9bn in January 2006. From January 2006 to January 2009, the notional amounts outstanding continuously increased until January 2010. The increase in the notional amount outstanding in January 2009 compared to January 2008 is likely due to activity between February 2008 and mid-September 2008 (as observed in Section 4.1). The 22 percent YoY drop from January 2009 to January 2010 was probably due to the influence of the crisis and to a much lesser extent, the Big Bang protocol. January 2011 saw a substantial increase with YoY notional amounts outstanding more than doubling compared to January 2010. There was a small YoY decline of 12 percent in January 2012 compared to January 2011, followed by another period of sustained growth

cumulating in a high of R50bn in January 2014. From January 2014 to January 2015, there was a 10 percent YoY drop to R45bn. January 2016 saw a peak at R54bn.

As with credit derivatives where the reporting bank was a protection buyer, the notional amounts outstanding of TRSs where the reporting bank was a protection seller represent a small percentage of the total credit derivatives market. The TRS market saw a period of growth between January 2009 and January 2012, but has since declined and in comparison to the market for CDSs and other credit derivatives, it remains relatively small.

In sharp contrast to the notional amounts outstanding of ‘other’ credit derivatives where the reporting bank is a protection buyer, the size of the market for other credit derivatives where the reporting bank is a protection seller is exceedingly small. According to Anonymous (2016), the reason for this is that South African banks sell protection to foreign banks primarily through CDSs and buy protection from local market participants either in the form of CDSs or CLNs. CLNs are classified as “other” credit derivatives. The notional amount outstanding in January 2005 was R2bn, spiking to R5bn in January 2008. This was followed by a period of decline lasting from January 2008 to January 2011, where it experienced overall growth until reaching a high of R6.8bn in January 2016. Unlike the market size of other credit derivatives where protection is bought, the market for other credit derivatives where protection is sold has been dwarfed by the CDS market where protection is sold since January 2008.

4.3 Gross fair values

Gross fair value could not be extracted from the DI430 form; therefore, it is only recorded from January 2008 onwards after the implementation of Basel II. Figure 5 below illustrates gross fair value for credit derivatives, distinguishing between gross positive fair value and gross negative fair value.

Figure 5: Gross fair value of credit derivatives: gross positive fair value vs. gross negative fair value.

Source: Compiled by researcher using data obtained from the SARB (2016)

Gross fair value more than doubled YoY from January 2008 to January 2009 from R6.6bn to R17.8bn, reaching its highest YoY level prior to January 2016. It then declined from January 2010 to 2012 and has been on an upward trajectory since reaching R17.6bn in January 2015 and R21.9bn in January 2016.

4.3.1 Gross positive fair value

Figure 6 below illustrates gross positive fair value (GPFV) and distinguishes between GPFV where the reporting bank is a protection seller and GPFV where the reporting bank is a protection buyer.

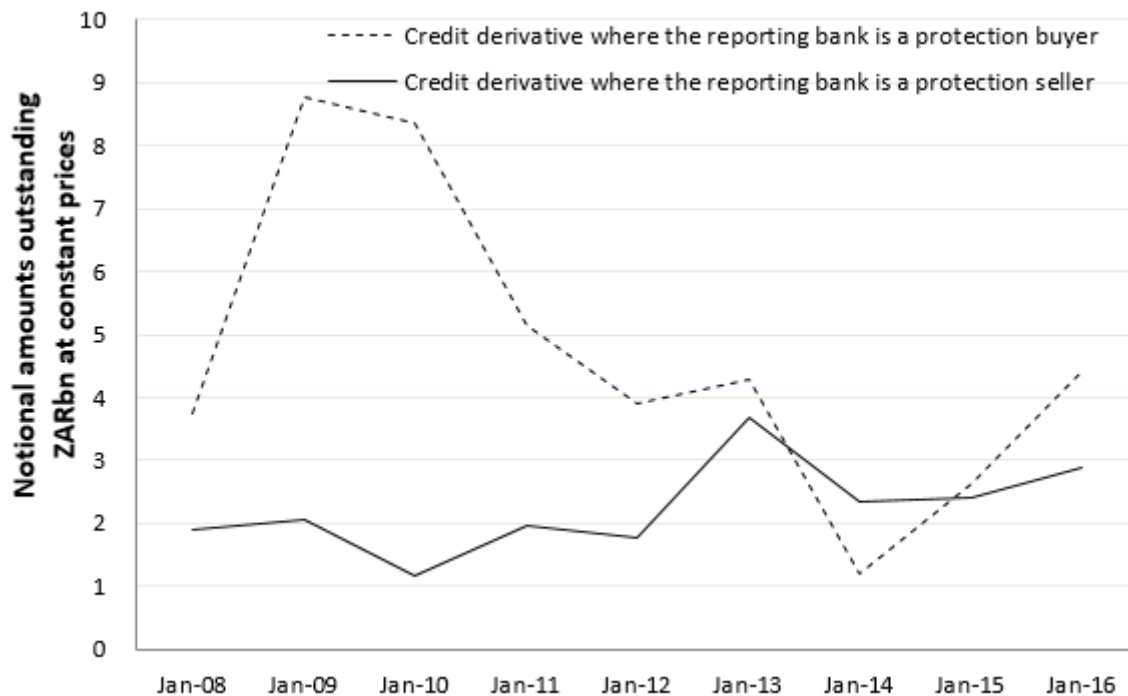

Figure 6: Gross positive fair value of protection bought versus protection sold

Source: Compiled by researcher using data obtained from the SARB (2016)

Overall, the GPFV of credit derivatives where the reporting bank was a protection buyer exceeded GPFV of credit derivatives where the reporting bank was a protection seller. The only exception was January 2014 where GPFV was R2.3bn for protection sold and R1.2bn for protection bought.

As at January 2009 and January 2010, the GPFV of protection bought, dwarfed the GPFV of protection sold. It is during this same period that there was a massive spike in ‘other’ credit derivatives where the reporting bank was a protection buyer (Figure 3). The author postulates that this increase was due to an increase in CLNs issued by South African banks and bought by local non-bank local market participants, such as asset managers and insurance firms. South African banks sell protection to local market participants by issuing CLNs and hedge their own risk with corresponding CDSs where the local bank is a protection buyer.

4.3.2. Gross negative fair value

Figure 7 below illustrates gross negative fair value (GNFV) and distinguishes between GNFV where the reporting bank is a protection seller and GNFV where the reporting bank is a protection buyer.

Figure 7: Gross negative fair value of protection bought versus protection sold

Source: Compiled by researcher using data obtained from the SARB (2016)

There was a large variation between the GNFV of credit derivatives where the reporting bank was a protection buyer and a protection seller. GNFV was extremely low at only R0.7bn in January 2008 for both protection bought and sold. It then rose sharply YoY tenfold to R7bn by January 2009. YoY GNFV then declined until January 2010 and further in January 2011. From January 2011, YoY GNFV increased steadily until it reached a peak in January 2016 of R14.6bn.

January 2014, 2015 and 2016 saw a large increase in YoY GNFV where the reporting bank was a protection buyer (an average of R7.6bn over the period) relative to YoY GNFV for protection sold (averaging at R4.5bn). This means that the CCR to local non-bank market participants, such as asset managers and insurance firms (excluding bilateral netting and collateral), has increased significantly YoY in the preceding three years (January 2014 – January 2016). It is possible the reporting of CLNs has been inconsistent, where some banks report only the underlying the CDS while others may report the full value of the CLNs as well. Reporting errors could explain this skewed representation of fair value during the YoY period January 2014 - 2016.

The establishment of a local trade repository with clear reporting requirements, which would likely run concurrently with the BA 350 forms for the initial phase, will strengthen the quality of the data collected and allow for the identification of reporting errors.

5. CONCLUSION

This article sought to provide transparency on the evolution of the size and composition of the South African credit derivatives market in its first decade, from 2005 to 2016. The period under study is prior to the implementation of post-crisis reforms apart from enforcement of CVA on non-centrally traded OTC derivatives in early 2015. The development of the size of the South African credit derivatives market can be separated into the following four distinct phases: infancy, pre-crisis growth, crisis aftershock and post-crisis growth. The infancy stage saw the birth of the credit derivatives market in South Africa in 2003³ up until 2007 when the Minister of Finance announced exchange control relaxation (Manuel, 2007). Up to that point, exchange controls had presented a significant barrier to growth in the market for all derivative asset classes (Adelegan, 2009). The pre-crisis growth period was characterized by an increase in the number of market participants and greater product innovation. The third period, beginning in late September 2008 and lasting for several months, was characterized by uncertainty and sluggishness in the market in the aftermath of the global financial crisis. The fourth period has seen continued growth after the crisis (since January 2010) culminating in January 2016 when the notional amounts outstanding for credit derivatives stood at R132.6bn (adjusted for inflation, using 2005 as the base year).

The South African credit derivatives market is currently too small to allow for a liquid interdealer CDS market. This lack of market liquidity will continue to restrict the range of local structured credit products on offer and would likely be further reduced if central clearing were mandated. The one-directional nature of risk transfer in the market would also severely negate the benefits of multilateral netting through central clearing. The credit derivatives market remains relatively small compared to the total OTC derivatives market, only making up between 0.31 percent and 0.77 percent during the period under study (January 2005 to January 2016), however, the relative increase in January 2016 may have been the result of the enforcement of a full CVA charge on local banks while some foreign counterparties remain exempt. The depth and liquidity of the South African credit derivatives market is most likely not high enough to warrant central clearing of this asset class. The costs associated with operating an authorized central counterparty (CCP) for the credit derivatives asset class would most likely outweigh the revenue that could be generated from offering services in South Africa for credit derivatives. Despite the continued post-crisis growth observed, the future of the South African credit derivatives market is uncertain as the regulatory environment continues to evolve. Despite the possible positive effect on the size of the credit derivatives market after the enforcement of CVA in early 2015, the liquidity and depth of the market remain limited. Mandatory central clearing, increased capital requirements (including adjustments to the calculation of CVA) and margining requirements for non-centrally cleared derivatives could stunt future growth as the cost of doing business rises. While the inconsistent application of regulation as well as the volatility in the calculation of CVA pose risks for the market and require further study. The CCR to local non-bank market participants, such as asset managers and insurance firms (excluding bilateral netting and collateral), has increased significantly YoY in the preceding three years (January 2014 – January 2016). Indicating a build-up of dealer exposure during this time, possibly increasing systemic risk.

³ The first time the researcher could find credit derivatives reported on the DI430 form was January 2003.

The current study was based upon the aggregated data published by the SARB, however, the enforcement of trade reporting would allow for the detailed analysis of granular contract level data going forward. Trade reporting improves transparency in the market and can lower CCR if the information is properly reported and properly used by authorities and the public. Trade reporting does not eliminate CCR, however, it allows supervisors to assess the build-up of systemic risk. Better trade reporting also enables supervisors to monitor previously unregulated market participants such as insurance firms, hedge funds and large corporates. Further study into the costs, benefits and unintended consequences of central clearing vs CVA and margining requirements on non-centrally cleared trades for the liquidity and size of the OTC credit derivatives market as well as the OTC derivatives market at large to inform South African regulators is needed.

ABSTRACT

In their commitment to implement G20 regulatory reforms to the over-the-counter derivatives market, a critical decision still faced by South African Authorities is which central clearing counterparty/ies (domestic or international), if any, to licence. Assuming an international counterparty is licenced, the foreign exchange rate exposure in value at risk and expected shortfall is calculated using a GARCH type model which accounts for volatility clustering and in addition, allows for the presence of regime-switching to be tested. Collateral demand calculated with the risk-sensitive models used by central clearing counterparties is sensitive to the market volatility scenarios, spiking during periods of market stress, highlighting the pro-cyclical nature of these requirements. Should an international clearing counterparty be licenced, South African Authorities should be prepared for a substantial increase in the demand for foreign currency. The transaction foreign exchange rate exposure was measured in USD and GBP, and it was found that the exposure demanded in USD was lower and relatively more stable than that in GBP.

Keywords: South African systemic risk, regulation of over-the-counter derivatives, exchange rate risk.

1. INTRODUCTION

Derivatives intensified losses during the 2008/09 Great Financial Crisis as market opacity created uncertainty about the exposure of some systemically important financial institutions from their credit derivative positions (Stulz, 2009, pp. 58–70). In an effort to improve transparency and risk transfer in the over-the-counter (OTC) derivatives market the G20 introduced various reforms including the central clearing of appropriate derivatives and margin requirements for non-centrally cleared derivatives. As a G20 member, South Africa has committed to implement market reform in line with the rest of the G20 nations so as to avoid international regulatory arbitrage (National Treasury, 2012). According to the Financial Stability Board, (FSB, 2019) “*differences in rule-making could lead to cross-border regulatory arbitrage and a potential build-up of risks in parts of the global financial system that go beyond those addressed by individual national authorities*”. However, not all reform decisions are made at an international level; domestic regulators must take some decisions after considering their market’s unique conditions. One such decision for South African Authorities⁴ is; how many central clearing counterparties (CCPs) should be

⁴ The regulatory landscape itself has changed in South Africa post-crisis. The Twin Peaks framework for financial sector regulation came into effect on 1 April 2018, governed by the Financial Sector Regulation Act, Act No. 9 of 2017. Twin Peaks saw the creation of two new regulators, the Prudential Authority (PA) which is housed within the South African Reserve Bank (SARB) and the Financial Sector Conduct Authority (FSCA) which replaces the Financial Services Board. The PA is responsible for prudential regulation and supervision as well as promoting financial sector stability. The FSCA is responsible for supervising market conduct. Unless otherwise specified, these two regulators, as well as National Treasury, will be referred to as South African “Authorities”.

licensed, if any, to provide central clearing services in the domestic market. Authorities indicated in June 2016 that they would allow a global CCP to establish a local office and they would not licence a domestic CCP other than the temporary license given to JSE Clear that would not be renewed (National Treasury, 2016). Although the legislation is in place to allow for a global CCP to be licensed, South African Authorities have not yet done so. South Africa has been one of the slowest members of the G20 to implement reforms to the OTC derivatives market.

Margining requirements on centrally cleared derivatives as well as contributions to a CCPs default fund (DF) would increase collateral demand for OTC derivatives providers (ODPs). The magnitude of the increase depends on the model inputs of the CCP's margin model. These demands should increase during times of market stress to cover the increasing CCR and potential future exposures (PFE); thus, the relationship between market stress and initial margin (IM) and DF requirements is pro-cyclical. A CCP may even choose to increase the number of IM calls it makes during times of increased market risk. Gibson & Murawski (2013) liken increasing margin requirements to a run on a bank, increasing liquidity demands when liquidity is scarce. They find that high margin rates when collateral is scarce increases the risk of default. Thus, when collateral is scarce, margining may increase default risk in contrast to the regulatory objective of reducing systemic risk. Licencing an international CCP exposes ODPs to exchange rate risk if IM and DF contributions are not accepted in ZAR. It is consequential to estimate the potential foreign exchange rate exposure of South African ODPs from clearing through an international CCP for macroprudential and microprudential stability. According to Heath, Kelly, & Manning (2012), an excess demand for HQLA in a foreign denominated currency could lead to a financial crisis because the local central bank is not the ultimate source of the needed liquidity. This is particularly true for institutions in the periphery of a central clearing network, for instance, small dealers like SA ODPs and domestic end-users. In addition, existing exchange control rules could restrict ODPs from complying with their collateral requirements. National Treasury may need to adjust exchange controls to accommodate this increase in demand and the SARB will need to be prepared to provide foreign exchange to the market in the event of a shortage of supply.

2. BACKGROUND AND LITERATURE REVIEW

Following the regulatory push post-crisis towards central clearing Duffie & Zhu (2011), in their seminal work, found that clearing through one CCP is always more efficient and cost-effective than multiple CCPs. Therefore, the stated intention of local Authorities to licence only one CCP is supported by Duffie & Zhu (2011) from a market efficiency perspective. Further work by Heller & Vause (2012), Heath et al. (2012) and Duffie, Scheicher, & Vuillemeys (2015) found that as the number of CCPs increase, multilateral netting benefits are reduced, and more collateral would need to be posted. Thus, the decision not to licence a domestic CCP minimises cost implications for domestic market participants because many existing foreign counterparties of the local ODPs are already clearing members of global CCPs.

Existing CCPs charge their clearing members IM and variation margin (VM) whilst prior to the Great Financial Crisis bilateral contracts seldom included VM and almost never included IM (International Swaps and Derivatives Association [ISDA], 2014). Since the crisis, however, exchanging VM has become common in bilateral contracts whilst the voluntary use of IM remains rare, this is true of the South African market as well (FSCA & PA, 2019b). In South Africa, margin

requirements on non-centrally traded derivatives were to be slowly phased in, with the first implementation phase starting in 2019, according to a (FSCA & PA, 2019a). However, the implementation schedule published in the 2019 draft document has been delayed by a year due to the Covid-19 crisis. The final implementation schedule for margin requirements for non-centrally cleared OTC derivative transactions was published on 2 June 2020. No ODP is anticipated to be large enough to be subject to mandatory IM posting on non-centrally cleared derivatives until 2023.

VM is held to protect against mark-to-market losses on a contract that is to limit the build-up of current exposure. The market values of derivative contracts vary continuously with the variation in the value of the underlying instrument. At any given moment one party's derivative contract is "in-the-money," i.e. the contract is an asset for the party who holds it, and the counterparty is, therefore "out-of-the-money," i.e. their derivative position is a liability. In a bilateral exchange, the party whose position is a liability transfers the VM straight to the party whose position is an asset, while when a contract is centrally cleared the CCP acts as a middle man, receiving the VM from the one-party and transferring it to the other. In a bilateral contract, both parties exchange IM to protect against PFE, which is defined as the maximum amount at a given confidence interval an investor could lose on their positions during a pre-specified period of time (Lopez et al., 2013). In the case of central clearing, IM is one-directional risk cover. Both parties to the initial contract post IM to the CCP, while the CCP does not post IM to its counterparties. IM is the first barrier to protecting a CCP against the default of one of its clearing members.

VM and IM are tools for mitigating CCR; however, it is possible for a counterparty's end of day loss position to exceed the VM and IM collateral its counterparty holds against the contract. The counterparty with the net loss position may then decide to default on its obligation. In the bilateral market, the defaulter's counterparty must then absorb the loss that exceeds the collateral it holds. Under central clearing, the CCP is still responsible for transferring the VM to the counterparty with the profit position, thereby absorbing the loss, as well as for finding a new counterparty to replace the defaulting counterparty. To cover such potential losses, CCPs demand from their clearing members an additional risk mitigation payment in the form of contributions to a default fund (DF). SwapClear (a subsidiary of LCH.Clearnet Ltd, which specialises in interest rate swaps) mandates that VM must be paid in the currency of the underlying exposure, i.e. ZAR to cover VM on ZAR denominated contracts. However, IM must be posted in GBP, USD, EUR and a few other eligible major currencies, currently excluding ZAR. Collateral can also be received in the form of acceptable securities subject to haircuts determined by LCH.Clearnet Ltd, currently, no ZAR denominated securities are classed as acceptable collateral (LCH.Clearnet Ltd, 2014). In addition, ZAR has been identified by LCH.Clearnet (2015) as one of four currencies that do not demonstrate a stable and/or strong relationship, therefore it is subject to a margin add-on to limit its use. Given the volatility of the ZAR already acknowledged by LCH.Clearnet, it may be deemed imprudent risk management for a foreign CCP, even one with an office in South Africa, to accept IM from its counterparties in ZAR. This would mean that local market participants would need to post collateral in foreign exchange or eligible securities, exposing them to exchange rate risk. In addition to posting margin to a CCP, local clearing members would also need to contribute to the DF. All contributions to SwapClear's DF are payable exclusively in GBP (LCH.Clearnet Ltd, 2013). South African banks are subject to exchange controls; thus, a sizeable increase in the

demand for foreign currency to meet collateral requirements may require South African Authorities to adjust foreign exchange regulation.

VM is passed from one counterparty to the other and since it is already common practice in bilateral contracts in South Africa its net aggregate impact on collateral demand in South Africa will be lower than IM and contributions to the DF. VM is also mostly posted in cash which is readily reused by dealers. According to Heath et al., (2012), the impact of IM on collateral demand will be “quantitatively much more important” than the demand as a result of VM. Thus, the effect of VM is beyond the scope of this study. DF contributions to CCPs as well as IM on centrally cleared and non-centrally cleared derivatives will increase the demand for high-quality liquid assets (HQLA).

In the bilateral OTC derivatives market structure, the interconnectedness of market participants and lack of counterparty relationship transparency were exposed as sources of systemic risk during the Great Financial Crisis (FSB, 2010). Central clearing increases the transparency of market participant’s derivative holdings compared to an opaque bilateral market structure and as a result, reduces systemic risk (Hull, 2010). When a party to a bilateral derivative contract defaults, the counterparty would usually want to replace the contract. However, since default would typically take place under conditions of financial stress with increasing concern over CCR, market liquidity may be reduced and if so, a replacement contract may come at a higher price, or it may not be possible to replace the contract at all in the bilateral market. CCPs are able to reduce this potential for market failure, where a contract cannot be replaced in times of financial stress, by facilitating the calm transfer of contracts from a defaulted clearing member to others by auction. Thus, CCPs can improve liquidity and reduce systemic risk during times when the bilateral market may seize up due to counterparty credit fears. CCPs can curtail price volatility and increases in systemic risk, which would result from the default of a large derivatives dealer in a bilateral market. However, not all derivative contracts are suitable for central clearing. According to the FSB (2010), only standardised products which have liquid markets and whose price is easy to attain and is generally agreed upon by the market are suitable for central clearing. If a product is not standardised, and/or does not have a sufficiently liquid market, and/or does not have an acceptable and easily available pricing source, then defaulted contracts are more complicated, if it is possible at all, to replace during times of market stress. Even a CCP would struggle to close out and replace such contracts leading to losses and potentially the failure of the CCP. The riskiness in underlying assets and the degree of heterogeneity in market participants both impact on the ability of a CCP to effectively perform its risk-sharing function (Antinolfi et al., 2022). Large CCPs are themselves systemically important institutions; thus, authorities should not force them to clear unsuitable contracts which could expose them to undue risk. Thus, the G20 only mandated central clearing for “standardised” OTC derivative contracts. Almost all interest rate derivatives (IRD) are highly contractually and operationally standardised, making them suitable for central clearing (FSB, 2010). The South African OTC derivatives market is one of the smallest in the G20 with IRD making up 88% of the market (as at end December 2018). Therefore, the initial central clearing mandate is likely to extend only to IRD as the other derivative asset classes in South Africa do not have as liquid markets with high levels of price transparency.

Some domestic trades already clear through foreign CCPs as a result of ODPs transacting with foreign counterparties who are already subject to mandatory central clearing requirements. In

January 2013, the first OTC derivative transaction involving a South African bank (Absa) and a foreign counterparty was cleared by LCH.Clearnet Ltd (FSB, 2013). However, no local ODPs are currently clearing members to any CCP; therefore, any transactions being centrally cleared are done so for local ODPs by clearing members offering client clearing services. SwapClear (a subsidiary of LCH.Clearnet Ltd, registered in the UK) is responsible for the central clearing of the majority of IRDs globally. Thus, given the fact 88% of South African OTC derivatives are IRD and SwapClear clears almost all IRDs globally, it would seem most likely that LCH.Clearnet Ltd will be given a licence to operate its SwapClear service in South Africa to maximise multilateral netting benefits. Another international CCP which could be licenced is the Chicago Mercantile Exchange (CME) which specialises in futures and commodities derivatives; however, it has a separate clearinghouse for IRD.

Dealer banks face higher liquidity requirements than they did before the Great Financial Crisis as a result of OTC derivatives reforms such as higher capital requirements, VM, IM, central clearing fees and trade reporting. This is in addition to the Basel III liquidity coverage ratio (LCR), net stable funding ratio and other post-crisis reforms (Sidanius & Zikes, 2012). Most dealers are large banks which means that higher collateral demands may result in lower credit extension by banks, which could reduce production in the real economy. A collateral shortage in the derivatives market could force dealers to limit market-making activities. Gibson & Murawski (2013) find that increased margin requirements may impact negatively on trading volume in the derivatives market, which could have devastating results for liquidity and the operation of this market. Thus, the ability of dealer banks to meet their increased collateral and liquidity demands has implications for systemic risk in the financial system. Despite the systemic weaknesses highlighted during the Great Financial Crisis, the derivatives market may serve an important role in the financial market by improving risk pricing and allowing for risk transfer (Cecchetti et al., 2009). The FSB (2010) notes that *“OTC derivatives benefit financial markets and the wider economy by improving the pricing of risk, adding to liquidity, and helping market participants manage their respective risks. However, it is important to address the weaknesses in these markets which exacerbated the financial crisis.”*

Participants in a bilateral OTC market are interconnected through a vast network of privately negotiated transactions, dominated by a few large dealers. The failure or default of a market participant can have large systemic risk implications as all of their counterparties attempt to replace their contracts while the market may be less liquid as a result of the default. Thus, market participants who act as dealers may pose a systemic risk to the derivatives market through their interconnectedness with other market participants even if their net positions are equal to zero, i.e. they have a “balanced book”. Conversely, dealers are exposed to systemic risk through their derivatives positions should one of their counterparties default. South African dealers or ODPs are primarily the country’s big five banks; therefore, systemic risk in the derivatives market could spill over into the larger financial system as it did in other countries during the Great Financial Crisis. The World Bank considers total bank assets to GDP as a good measure of the depth of a country’s financial system. Total bank assets as of December 2015 was 4.8 trillion ZAR (SARB, 2016) whilst GDP for 2015 was estimated at 4.5 trillion ZAR. Thus, South African banks’ balance sheets are large in relation to the country’s economy. This makes it important to quantify the collateral required for South African ODPs in the derivatives market to comply with incoming regulations.

In addition, the local market's exposure to foreign currencies is likely to increase during times of local market stress through the potential depreciation of the ZAR (possibly as a result of a risk-averse flight to reserve currencies or as a result of a deterioration of South African fundamentals). In addition, shocks to global liquidity typically involve large foreign exchange liquidity shortfalls, barring intervention from authorities (Committee on the Global Financial System [CGFS], 2013). These factors of increased demand for collateral and the possible short-term shortages of HQLA in times of volatility could lead to a crippling shortage of liquidity for financial institutions. A shortage of liquidity could result in the bankruptcy of otherwise solvent institutions, in other words, where assets exceed liabilities. In the case of systemically important financial institutions, their bankruptcy could result in complete market failure. This then places a burden on the SARB to be prepared to provide liquidity to the market in its function as the lender of last resort. According to van Wyk, Botha, & Goodspeed (2019), the lender of last resort function is fulfilled by *"a country's central bank in extending credit to banks or to other entities in unusual circumstances involving a national or regional emergency, where failure to obtain credit would have a severe adverse impact on the economy."* This liquidity assistance should only be extended when the failure of the entity poses a systemic threat, and when the entity is otherwise solvent.

3. METHODOLOGY

South African Authorities have indicated their intention to mandate central clearing for eligible products, thus it is assumed that all IRD are cleared through a single global CCP and subject to exchange rate risk. The potential magnitude of collateral demands on South African ODPs that would result from the enforcement of IM and DF contributions on centrally cleared derivatives (using a CCP's margin model) are estimated in ZAR in Kennedy-Palmer (2021). These estimates are used to quantify and examine the foreign exchange rate risk that ODPs would be exposed to through an international CCP. The two currencies (against the ZAR) considered in this analysis are the GBP as it is the preferred currency accepted by SwapClear as well as the USD because it is still the world's top reserve currency (IMF, 2019). An estimation of risk is crucial to limiting the misallocation of capital, for this reason, the presence of regime-switching, asymmetry, and different conditional distributions are tested for. This study investigates the in-sample accuracy of the ARCH, GARCH, E-GARCH, GJR-GARCH and T-GARCH models for up to four regimes and six conditional distributions for both currencies. The top-performing model is then used to estimate the value at risk (VaR) and expected shortfall (ES) for both exchange rates at a 99% confidence level to evaluate the exchange rate risk exposure to local ODPs through their cleared derivative portfolios.

This study employs a univariate approach to modelling foreign exchange rate volatility as well as measuring exchange rate risk because it is desirable to measure the exchange rate exposure for each of the two selected exchange rates individually. Papaioannou (2006) identifies VaR as the most appropriate approach for measuring foreign exchange rate risk. Given the recent regulatory focus on ES over VaR, both will be calculated. Papaioannou (2006) finds that when measuring exchange rate risk, the typical holding period is one day, and the confidence levels are typically 99% and 95%. For the sake of prudence, this study measures exchange rate risk at the 99% confidence level for VaR and ES.

Pérignon, Deng, & Wang (2008) find that a GARCH type model is superior for calculating VaR because it accounts for volatility clustering. The two exchange rates will be fitted to a total of 120 GARCH-type models to identify the best performing in sample-fit for each series. The ARCH, GARCH, E-GARCH, GJR-GARCH and T-GARCH, with six conditional distributions and up to a maximum of four regimes will be tested. The best performing GARCH type model for each exchange rate will then be used to forecast the 99% VaR and ES for one period ahead. The percentage daily loss for each exchange rate under the appropriate number of regimes will provide a band for the potential economic exposure to an international CCP from IM and DF demands denominated in GBP or USD.

4. RESULTS AND DISCUSSION

The Akaike information criterion (AIC) and Bayesian information criterion (BIC) goodness-of-fit tests are used to select the preferred in-sample model for both exchange rates. The lowest AIC and BIC indicate the model which provides the best fit for the data. The model with the lowest AIC is the one that maximises the likelihood function. The BIC imposes a greater penalty on the number of parameters than the AIC; therefore, it favours parsimony. The results of the 120 models tested for each of the two exchange rates are available on request. The AIC and BIC both select the 3-State T-GARCH with a GED distribution for the ZARGBP data. Thus, the ZARGBP data exhibits regime-switching, asymmetry in response to past negative observations as well as a non-normal distribution. However, the AIC and BIC select different models for the ZARUSD data. The AIC prefers the 3-State GJR-GARCH with Skewed Student's t distribution while the BIC prefers the 1-State GJR-GARCH with Skewed Student's t distribution. Thus, the ZARUSD data exhibits asymmetry in response to past negative observations and a skewed non-normal distribution; however, the presence of regime-switching is uncertain. The two top-performing models for the ZARUSD exhibit skewness while the unilaterally selected model for the ZARGBP does not.

The GJR-GARCH of (Glosten, Jagannathan, & Runkle, 1993) reflects the asymmetric nature of responses by defining the conditional variance as a linear piecewise function.

$$\sigma_{k,t}^2 = \alpha_{0,k} + (\alpha_{1,k} + \alpha_{2,k} \mathbb{I}\{r_{t-1} < 0\}) r_{t-1}^2 + \beta_k \sigma_{t-1}^2$$

Equation 1: GJR-GARCH (1,1)

where $\sigma_{k,t}^2$ is the time-varying variance of a variable for period t, $\alpha_{0,k}$ is the constant and r_{t-1}^2 is the squared percentage change in the differenced interest rate. $\sigma_{k,t-1}^2$ is the previous period's variance. $\alpha_{1,k}$ captures the sign effect, and $\alpha_{2,k}$ indicates the degree of asymmetry. $\mathbb{I}\{\cdot\}$ is an indicator function which takes the value 1 if $\{r_{t-1} < 0\}$, otherwise it takes the value 0. The persistence is captured by β_k . To ensure positivity the following must hold: $\alpha_{0,k} > 0$, $\alpha_{1,k} > 0$, $\alpha_{2,k} \geq 0$ and $\beta_k \geq 0$. The persistence is captured by $\alpha_{1,k} + \alpha_{2,k} E[\eta_{k,t}^2 \mathbb{I}\{\eta_{k,t} < 0\}] + \beta_k$. Covariance-stationarity in each regime requires $\alpha_{1,k} + \alpha_{2,k} E[\eta_{k,t}^2 \mathbb{I}\{\eta_{k,t} < 0\}] + \beta_k < 1$

Zakoian's Threshold GARCH (T-GARCH) was developed in 1994. The conditional volatility is the dependent variable instead of the conditional variance.

$$\sigma_{k,t} = \alpha_0 + \alpha_{1,k} r_{t-1} \mathbb{I}\{r_{t-1} \geq 0\} + \alpha_{2,k} r_{t-1} \mathbb{I}\{r_{t-1} < 0\} + \beta_k \sigma_{t-1}$$

Equation 2: T-GARCH (1,1)

To ensure positivity the following must hold: $\alpha_{0,k} > 0$, $\alpha_{1,k} > 0$, $\alpha_{2,k} > 0$ and $\beta_k \geq 0$. The volatility persistence is captured by $\alpha_{1,k}^2 + \beta_k^2 - 2\beta_k(\alpha_{1,k} + \alpha_{2,k})E[\eta_{t,k} \mathbb{I}\{\eta_{t,k} < 0\}] - (\alpha_{1,k}^2 - \alpha_{2,k}^2)E[\eta_{t,k}^2 \mathbb{I}\{\eta_{t,k} < 0\}] + \beta_k$. Covariance-stationarity in each regime requires $\alpha_{1,k}^2 + \beta_k^2 - 2\beta_k(\alpha_{1,k} + \alpha_{2,k})E[\eta_{t,k} \mathbb{I}\{\eta_{t,k} < 0\}] - (\alpha_{1,k}^2 - \alpha_{2,k}^2)E[\eta_{t,k}^2 \mathbb{I}\{\eta_{t,k} < 0\}] + \beta_k < 1$

The effect of the previous period's differenced interest rate on the conditional variance depends on its sign. It is α_1 when r_{t-1} is positive, and when negative it is $\alpha_1 + \alpha_2$. Therefore α_2 is positive when a leverage effect is present.

A summary of the top three models selected are presented in table 1 below.

Table 1: Details of the 3-State T-GARCH, 3-State GJR-GARCH and 1-State GJR-GARCH

| Coefficients | ZARGBP | | ZARUSD | | ZARUSD | |
|----------------|---------------------|------------|------------------------|------------|------------------------|-----------|

All three models are covariance-stationary in each state. Covariance-stationarity in each state for the GJR model requires $\alpha_{1,k} + \alpha_{2,k}E[|\eta_{k,t}^2 \mathbb{I}\{\eta_{k,t} < 0\}|] + \beta_k < 1$. Covariance-stationarity requires $\alpha_{1,k}^2 + \beta_k^2 - 2\beta_k(\alpha_{1,k} + \alpha_{2,k})E[\eta_{t,k} \mathbb{I}\{\eta_{t,k} < 0\}] - (\alpha_{1,k}^2 - \alpha_{2,k}^2)E[\eta_{t,k}^2 \mathbb{I}\{\eta_{t,k} < 0\}] + \beta_k < 1$ for a T-GARCH. The volatility persistence for each state of a T-GARCH is calculated as follows:

$$\alpha_{1,k}^2 + \beta_k^2 - 2\beta_k(\alpha_{1,k} + \alpha_{2,k})E[\eta_{t,k} \mathbb{I}\{\eta_{t,k} < 0\}] - (\alpha_{1,k}^2 - \alpha_{2,k}^2)E[\eta_{t,k}^2 \mathbb{I}\{\eta_{t,k} < 0\}] + \beta_k$$

The volatility persistence for the GJR-GARCH is calculated by $\alpha_{1,k} + \alpha_{2,k}E\left[|\eta_{k,t}^2\mathbb{I}\{\eta_{k,t} < 0\}|\right] + \beta_k$. In both equations, $E\left[|\eta_{k,t}^2\mathbb{I}\{\eta_{k,t} < 0\}|\right] = 1/2$ for an unskewed distribution and is dependent on the degree of asymmetry as per (Trottier & Ardia, 2016) for a skewed distribution. The volatility persistence for each model per state is presented in tables 2 – 4.

Table 2: The persistence in volatility per state of the 3-State T-GARCH GED for the ZARGBP data

| Volatility persistence of each state of the 3-State T-GARCH GED | |
|---|-----------|
| State 1 | 0.0017689 |
| State 2 | 0.8099124 |
| State 3 | 0.7847350 |

| State 1 | 0.9998589 |
| State 2 | 0.7949048 |
| State 3 | 0.9808084 |

Source: Author's calculations

The volatility persistence for the single state GJR-GARCH is almost indistinguishable from that of the 3rd state of the 3-State GJR-GARCH. However, it does not represent the persistence of other two states, either under or overstating the persistence, indicating that the single state model is unable to capture the full extent of the volatility dynamics in the ZARUSD data. The transition probability matrices for the two multi-state models are presented in tables 5 and 6. The transition probabilities for both multi-state models are not $p_{11} = 1 - p_{22}$, therefore rejecting the null hypothesis used by Engel & Hamilton (1990)⁵. Thus, confirming that the multi-state models do not follow a random walk and the data exhibits regime-switching behaviour. This result indicates that the 3-State model is preferred over the 1-State model for the ZARUSD data.

Table 5: The transition probability matrix of the 3-State T-GARCH GED for the ZARGBP data

| | t+1 k=1 | t+1 k=2 | t+1 k=3 |
|-------|------------|-----------|-----------|
| t k=1 | 0.06337951 | 0.5273493 | 0.4092712 |
| t k=2 | 0.10140738 | 0.8798137 | 0.0187789 |
| t k=3 | 0.02379537 | 0.3639686 | 0.6122360 |

Source: Author's calculations

⁵ Engel & Hamilton's (1990) pioneering work finds that there are long swings in the quarterly USD exchange rate against major currencies between 1973 and 1988, which persist over time, rejecting the random walk hypothesis. They do so by testing the null hypothesis that the change in the exchange rate during the current period is independent of the state in the previous period, i.e. $H_0: p_{11} = 1 - p_{22}$. In other words, the null hypothesis is that exchange rates follow a martingale (where the expected value of the next random variable in a sequence, given all prior values, is its current value) and the alternative is the presence of segmented trends. If the null holds, the probability of currently being in a state does not depend on the state of the previous period; thus, the process follows a random walk. They reject the null and find that long swings are captured by a Markov-switching process which is a feature of changing underlying economic conditions. Engel & Hamilton find that a two regime Markov-switching process outperforms a random walk both in-sample and out-of-sample in the short-term.

Table 6: The transition probability matrix of the 3-State GJR-GARCH SSTD for the ZARUSD data

| | $t+1 k=1$ | $t+1 k=2$ | $t+1 k=3$ |
|---------|-------------|------------|----------------------------|

Source: Author's calculations

For the ZARGBP data, State 1 represents a period of the lowest mean volatility combined with the highest maximum volatility, indicating that volatility shocks in this state are particularly large and rare. The volatility persistence of State 1 is extremely low at 0.1769% and reports only a 6.3% chance of remaining in State 1 in $t+1$ if initially in State 1. State 2 represents the more moderate state with the lowest maximum volatility and the lowest differential between the mean and maximum volatility. State 2 is the most persistent state, the probability of remaining in State 2 in $t+1$ if initially in State 2 is 88%, and it has the highest volatility persistence of 80.99%. State 3 characterises the highest mean volatility and a high maximum volatility. The probability of remaining in State 3 in $t+1$ if initially in State 3 is 61% and its volatility persistence is 78.47%.

The single state ZARUSD reports a mean and maximum volatility that represents an approximate average of the volatilities in three states of the multi-state model. It neither captures the lowest nor highest volatilities of the three-state model. The single state model also reports a high volatility persistence of 98.08%. State 1 of the 3-State GJR-GARCH exhibits the smallest differential between the mean and maximum volatility as well as the lowest maximum volatility amongst the three states. It has a high volatility persistence of 99.99% and a 0.14% probability of remaining in State 1 in $t+1$ if initially in State 1. State 2 reports the lowest mean volatility combined with the highest maximum volatility. There is a 28% probability of remaining in State 2 in $t+1$ if initially in State 2, and the volatility persistence is the lowest for this state at 79.49%. State 3 reports the highest mean volatility and a maximum volatility slightly smaller than that of State 2. The volatility persistence is slightly lower than that of State 1 at 98.08% and the probability of remaining in State 3 in $t+1$ if initially in State 3 is 34%.

The 10-day ahead VaR and ES for all three models per state are illustrated below in tables 7 – 9. The influence of the volatility dynamics in each state can be seen through the percentage daily loss as well as the fluctuation of VaR and ES over the 10-day ahead period. The states with the smaller differential between the mean and maximum volatility and higher volatility persistence tend to fluctuate around the mean percentage daily loss. See the VaR and ES diagrams of State 2 for the ZARGBP model as well as the single state model for ZARUSD and State 1 of the 3-State ZARUSD model. These diagrams exhibit a zig-zag type pattern, displaying a high reversion to the mean percentage daily loss as well as a high volatility persistence. The states with a high differential between mean and maximum volatility and lower volatility persistence, on the other hand, tend to exhibit more of an explosive process, either increasing or decreasing the loss as the number of steps ahead increases. For example, see the VaR and ES diagrams of States 1 and 3 for the ZARGBP model as well as States 2 and 3 for the 3-State ZARUSD model for illustrations of a diversion from the mean percentage daily loss through time. The percentage daily loss is influenced more by the mean volatility than by the maximum volatility in each state, indicating that extreme tail losses are large and rare.

The 1 step ahead VaR and ES are used to estimate the foreign exchange rate exposure due to IM and DF requirements per market volatility scenario and state for both currencies.

4.1 Foreign exchange rate exposure denominated in GBP

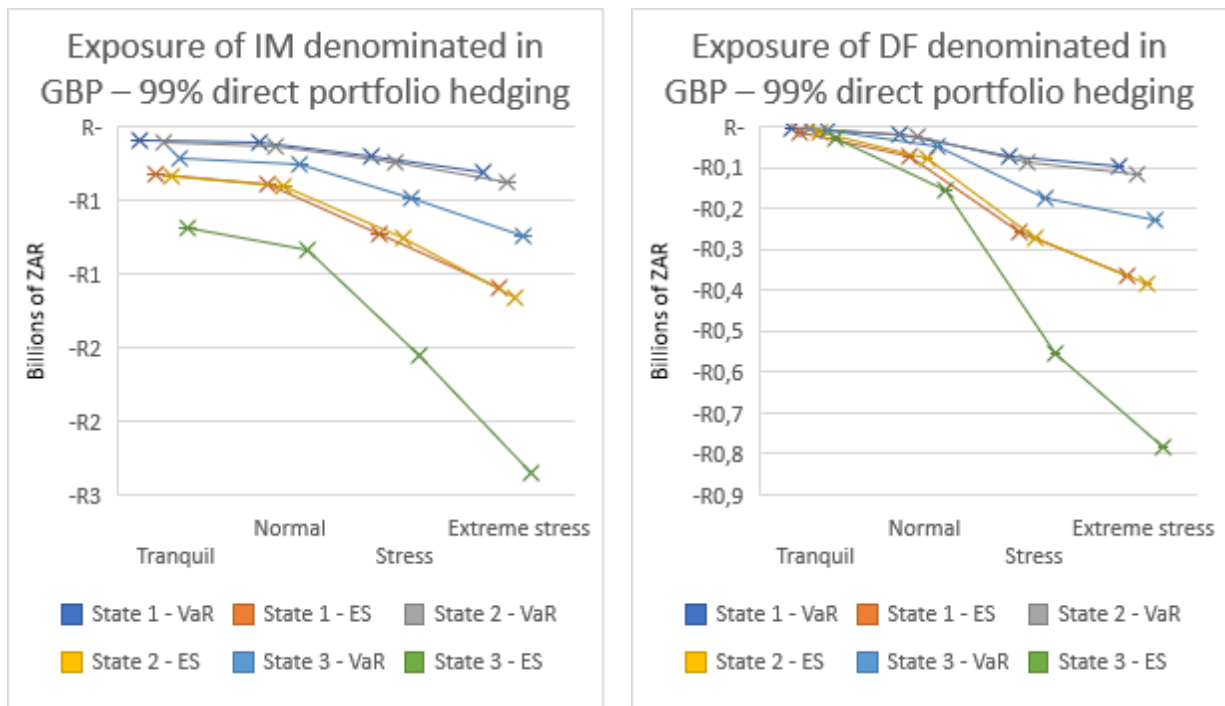

Figure 8: Foreign exchange rate exposure of IM denominated in GBP – 99% direct portfolio hedging

Figure 9: Foreign exchange rate exposure of DF denominated in GBP – 99% direct portfolio hedging

Source: Author's calculation

Figure 11: Foreign exchange rate exposure of IM denominated in GBP – 90% direct portfolio hedging

Source: Author's calculation

See figure 8, which illustrates the 1-day ahead foreign exchange rate exposure of IM requirements denominated in GBP under a 99% direct portfolio hedging assumption across volatility scenarios and per state of the 3-State T-GARCH GED. The exposure increases as the market volatility increases and ES is more sensitive to changing market conditions than VaR, as is to be expected. States 1 and 2 report similar foreign exchange rate exposure. State 1 has the lowest VaR and ES 1 step ahead and a sharply declining exposure as the number of steps ahead increase. It has an incredibly small volatility persistence, meaning that shocks quickly dissipate. Despite being characterised by the highest maximum volatility, State 1 also exhibits the lowest mean volatility. This indicates that in this state, shocks are very large; however, they are rare and quickly dissipate. State 2 is characterised by the lowest maximum volatility, the smallest differential between mean and maximum volatility and the highest volatility persistence, the VaR and ES follows a mean-reverting process. The 1-day foreign exchange rate VaR of IM demands denominated in GBP is 0.09 and 0.11 billion ZAR in the tranquil market conditions, rising to 0.31 and 0.38 billion ZAR for States 1 and 2 respectively. The ES of IM demands is 0.32 and 0.34 billion ZAR in tranquil market conditions, rising to 1.1 and 1.16 billion ZAR for States 1 and 2 respectively under extreme market stress. State 3, in contrast, represents a high-risk state, with the highest mean volatility and a high maximum volatility. The volatility persistence is slightly lower than that of State 2, and the exposure increases as the number of steps ahead increase, displaying a more explosive exchange rate risk. The IM VaR in State 3 increases from 0.22 billion ZAR under tranquil market conditions to 0.74 billion ZAR under extreme market stress, while the ES rises from 0.69 to 2.35 billion ZAR.

Figure 9 illustrates the foreign exchange rate exposure of DF requirements denominated in GBP under a 99% direct portfolio hedging assumption. If South African ODPs' DF contributions did not exceed the minimum contribution required by SwapClear then the foreign exchange rate exposure would be represented by the VaR under normal market conditions. The DF VaR for States 1 and 2 respectively increases from 0.003 and 0.004 to 0.09 and 0.12 billion ZAR when moving from tranquil to extreme market stress conditions. Conversely, when transitioning from tranquil to extreme market stress conditions, the DF ES increases from 0.013 and 0.014 to 0.36 and 0.38 billion ZAR for States 1 and 2, respectively. In State 3, the VaR increases from 0.01 to 0.23 billion ZAR when transitioning to extreme market stress from tranquil market conditions and the ES from 0.03 to 0.78 billion ZAR. It is clear that State 3 represents the high-risk state with a high exposure that increases as the number of steps ahead increases. Combining the IM and DF requirements denominated in GBP, the potential 1-day loss when in State 3 increases from 0.23 and 0.72 billion ZAR under tranquil market conditions for VaR and ES respectively, to 0.97 and 3.13 billion ZAR under extreme market stress.

Changing the direct portfolio hedging assumption from 99% to 90% has a much higher impact on IM and DF requirements than changes in market volatility. As such, the 90% direct hedging portfolio has a much larger exchange rate exposure than the 99% direct hedging portfolio, see figures 10 and 11. The potential combined IM and DF 1-day loss when in State 3 assuming 90% direct hedging increases from 1.87 and 5.94 billion ZAR under tranquil market conditions for VaR and ES respectively, to 8.93 and 28.43 billion ZAR under extreme market stress.

The combined upper and lower bound VaR and ES GBP exchange rate exposure expressed in billions of ZAR for both direct hedging assumptions across volatility scenarios are presented below in table 10. State 3 represents the upper bound for ZARGBP exchange rate exposure, and State 1 represents the lower bound for ZARGBP exchange rate exposure. The VaR amount in billions of ZAR is presented on the left side of the hyphen, and the ES amount in billions of ZAR to the right side.

Table 10: VaR and ES upper and lower bounds for foreign exchange rate exposure in billions of ZAR when posting IM and DF denominated in GBP

| VaR and ES upper and lower bounds for IM and DF denominated in GBP | | | | |
|--|-----------------|---------------|---------------|-----------------------|
| | Tranquil market | Normal market | Market stress | Extreme market stress |
| 99% direct hedging Lower bound | 0.093 – 0.33 | 0.13 – 0.46 | 0.27 – 0.98 | 0.40 – 1.46 |
| 99% direct hedging Upper bound | 0.23 – 0.72 | 0.31 – 0.98 | 0.66 – 2.11 | 0.97 – 3.13 |
| 90% direct hedging Lower bound | 0.77 – 2.77 | 1.11 – 4.01 | 2.48 – 8.93 | 3.68 – 13.28 |
| 90% direct hedging Upper bound | 1.87 – 5.94 | 2.7 – 8.59 | 6.01 – 19.12 | 8.93 – 28.43 |

4.2 Foreign exchange rate exposure denominated in USD

Figure 12: Foreign exchange rate exposure of IM denominated in USD – 99% direct portfolio hedging

Source: Author's calculation

Figure 13: Foreign exchange rate exposure of DF denominated in USD – 99% direct portfolio hedging

Figure 14: Foreign exchange rate exposure of IM denominated in USD – 90% direct portfolio hedging

Source: Author's calculation

Figure 15: Foreign exchange rate exposure of DF denominated in USD – 90% direct portfolio hedging

Source: Author's calculation

Figure 12 represents the 1-day ahead foreign exchange rate exposure of IM requirements denominated in USD under a 99% direct portfolio hedging assumption. The VaR and ES per the

three states of the 3-State GJR-GARCH SSTD (labelled State 1-3), as well as the single state of the 1-State GJR-GARCH SSTD (labelled Single state), are presented across volatility scenarios. State 1 of the multi-state model characterises the largest exposure at 1 step ahead, however, with the lowest differential between mean and maximum volatility and the highest volatility persistence, there is a strong reversion to the mean percentage daily loss meaning that the exposure in this state is relatively constant through time. The VaR ranges between 0.16 and 0.56 billion ZAR as market conditions transition from tranquil to extreme market stress, conversely the ES ranges between 0.56 and 1.92 billion ZAR. State 2 of the multi-state model is characterised by the lowest mean volatility, the highest maximum volatility, the lowest volatility persistence and the lowest VaR and ES for the portfolio denominated in USD. Thus, indicating that shocks in this state are large, rare and quickly dissipate. The VaR ranges between 0.07 and 0.25 billion ZAR as market conditions transition from tranquil to extreme market stress, conversely the ES ranges between 0.21 and 0.73 billion ZAR. State 3 exhibits the highest mean volatility and the second-highest maximum volatility. Despite a volatility persistence slightly below that of State 1, the differential between the mean and maximum volatility is high, resulting in a weak reversion to the mean percentage daily loss and an escalating exposure as the number of steps ahead increase. The VaR ranges between 0.14 and 0.46 billion ZAR as market conditions transition from tranquil to extreme market stress, conversely the ES ranges between 0.42 and 1.43 billion ZAR. The single state model reports VaR and ES exposures close to those reported by State 3 of the multi-state model. It is characterised by a small differential between mean and maximum volatility as well as an extremely high volatility persistence, as such it exhibits a strong reversion to the mean percentage daily loss. The VaR ranges between 0.14 and 0.49 billion ZAR as market conditions transition from tranquil to extreme market stress, conversely the ES ranges between 0.47 and 1.62 billion ZAR. The single state ZARUSD model does not capture the extreme tail risk captured by the 3-state model. Therefore, although the presence of regime-switching is indeterminate, regime-switching models provide more information about possible tail losses.

Figure 13 illustrates the foreign exchange rate exposure of DF requirements denominated in USD under a 99% direct portfolio hedging assumption. In State 1, the DF VaR increases from 0.01 to 0.17 billion ZAR when transitioning to extreme market stress from tranquil market conditions and the ES from 0.02 to 0.64 billion ZAR. The transition from tranquil to extreme market stress results in an increase in VaR from 0.003 to 0.08 billion ZAR and in ES from 0.01 to 0.24 billion ZAR in State 2. The DF VaR for State 3 and the single regime state respectively increases from 0.005 and 0.01 to 0.14 and 0.15 billion ZAR when moving from tranquil to extreme market stress conditions. Conversely, when transitioning from tranquil to extreme market stress conditions, the DF ES increases from 0.02 and 0.02 to 0.48 and 0.54 billion ZAR for State 3 and the single regime state, respectively. State 1 represents the high exposure state, and a quick reversion to the mean daily percentage loss, meaning the exposure stays relatively constant throughout the 10 steps ahead illustrated in table 8. Combining the IM and DF requirements denominated in USD, the potential 1-day loss when in State 1 increases from 0.17 and 0.58 billion ZAR under tranquil market conditions for VaR and ES respectively, to 0.73 and 2.65 billion ZAR under extreme market stress. As for the GBP foreign exchange exposure discussed above, changing the direct portfolio hedging assumption from 99% to 90% has a much larger impact on IM and DF requirements than changes in market volatility. As such, the 90% direct hedging portfolio has a much larger exchange rate exposure than the 99% direct hedging portfolio, see figures 14 and 15 The potential 1-day loss

when in State 1, assuming 90% direct hedging, increases from 1.41 and 4.85 billion ZAR under tranquil market conditions for VaR and ES respectively, to 6.71 and 23.23 billion ZAR under extreme market stress. The upper and lower bound VaR and ES expressed in billions of ZAR for both direct hedging assumptions across volatility scenarios is presented below in table 11. State 1 represents the upper bound for ZARUSD exchange rate exposure, and State 2 represents the lower bound for ZARUSD exchange rate exposure. The VaR amount in billions of ZAR is presented on the left side of the hyphen, and the ES amount in billions of ZAR to the right side for IM and DF combined.

Table 11: VaR and ES upper and lower bounds for foreign exchange rate exposure in billions of ZAR when posting IM and DF denominated in USD

| VaR and ES upper and lower bounds for IM and DF denominated in USD | | | | |
|--|-----------------|---------------|---------------|-----------------------|
| | Tranquil market | Normal market | Market stress | Extreme market stress |
| 99% direct hedging Lower bound | 0.073 – 0.22 | 0.11 – 0.31 | 0.22 – 0.65 | 0.33 – 0.97 |
| 99% direct hedging Upper bound | 0.17 – 0.58 | 0.06 – 0.81 | 0.5 – 1.72 | 0.73 – 2.56 |
| 90% direct hedging Lower bound | 0.08 – 1.84 | 0.9 – 2.67 | 2 – 5.94 | 2.98 – 8.83 |
| 90% direct hedging Upper bound | 1.41 – 4.85 | 2.03 – 7.02 | 4.51 – 15.62 | 6.71 – 23.23 |

5. CONCLUSION

The one day ahead transaction foreign exchange rate exposure is estimated for local ODPs through membership to an international CCP, assuming either GBP or USD denominated collateral requirements. A contribution of this study is the analysis of volatility dynamics, accounting for regime shifts, asymmetry in the reaction to past negative observations and different conditional distributions. The results strongly indicate the presence of regime-switching in the GBP data; however, the presence of regime-switching in the USD data is inconclusive. Regime-switching does appear to increase explanatory power when there is heterogeneity in a series, and its presence cannot be rejected for the USD data.

A key finding is the relatively higher exchange rate risk, as measured in VaR and ES, for GBP over USD against the ZAR during the period under observation, this is supported by the relatively higher volatility found in the GBP data. As a result of the relatively higher exchange rate risk it may be beneficial for South African ODPs to become clearing members of CME based in the USA, the second largest clearer of IRDs rather than the UK based SwapClear. The relative netting benefits of SwapClear would have to be fully offset by the exchange rate risk differential of transacting only in USD. Although IRDs are the largest derivative asset class in South Africa, the netting benefits for other derivative classes might be larger at CME than at SwapClear again making it a worthwhile consideration. Brexit provides another reason to consider the second largest clearer of IRDs (CME) over the largest. SwapClear grew to be the largest clearer of IRDs because of its ability to “passport” into the rest of the EU. Following Brexit however, the EU has not granted equivalence to SwapClear which could threaten its market dominance.

The cause of the relative stability in the ZARUSD over the ZARGBP is an area for future research; however, the relative stability of the ZARUSD may be due to the USD’s position as the world’s

top reserve currency. The disparity in the volatility of the two exchange rates against the ZAR indicates that the ZAR volatility dynamics may be driven primarily by foreign rather than domestic shocks. This suggests that although domestic political stability would reduce foreign exchange rate volatility, external factors which cannot be influenced by the South African government such as global economic shocks and commodity prices may have a greater impact.

The impact of regime specific volatility dynamics on exchange rate risk measured by VaR and ES is explored. For both exchange rates studied during the period under observation, it was found that the higher the mean volatility, the higher the exchange rate risk, and therefore the larger the exposure. The high exposure state for the ZARUSD data (State 1 of the multi-state model) exhibits an extremely high volatility persistence and a strong reversion to the mean percentage daily loss, indicating that even during times of high USD exchange rate exposure, the VaR and ES are relatively stable through time. In contrast, the high exposure state for the ZARGBP data (State 3) exhibits a lower volatility persistence and a weak reversion to the mean, displaying a more explosive exchange rate risk. This indicates a deviation from the mean percentage daily loss in the high ZARGBP exposure state resulting in increasing VaR and ES through time.

Major depreciations and high South African exchange rate volatility appear to have occurred simultaneously between 2001 and 2018 (Kennedy-Palmer, 2021), while the research results show that the higher the mean volatility, the higher the exchange rate risk. Therefore, a shock may lead to a simultaneous depreciation, an increase in exchange rate volatility and an increase in exchange rate risk, compounding the increase in collateral requirements. In addition, a large global shock may decrease foreign exchange market efficiency in developing markets, decreasing liquidity and the supply of HQLA (CGFS, 2013). An international CCP exposes South African ODP's to economic exchange rate exposure because the amount payable increases when there is an increase in the volatility of the foreign exchange rate as well as a depreciation of the rand. A sustained period of depreciation would expose ODPs to increasing economic exchange rate risk, which is difficult to hedge against. Thus, understanding the volatility dynamics of foreign exchange rates and its effect on the value of foreign currency-denominated capital requirements is important for individual ODPs in order to limit the misallocation of capital as well as by monetary and fiscal Authorities to limit systemic risk.

FACTORS HINDERING THE PROGRESS AND EFFECTIVENESS OF USING DEOXYRIBONUCLEIC ACID TECHNOLOGY TO COMBAT STOCK THEFT IN SELECTED AREAS OF KWAZULU-NATAL PROVINCE

W. Maluleke

University of Limpopo, Sovenga, South Africa

ABSTRACT

The existence of factors hindering the progress and effectiveness of using Deoxyribonucleic Acid (DNA) technology to combat stock theft in the selected areas of KwaZulu-Natal (KZN) Province is crystal clear. The use of this technology seems to be a new concept for the Anti-Stock Theft Unit of the South African Police Service in this province. This inadequacy adversely affects the delicate economy of small-scale and commercial farming sectors. The current study applied descriptive and exploratory research designs, aided by qualitative research approach. Fifty-seven (57) participants were purposively selected and were all subjected to semi-structured Focus Group Discussions (FGDs) and Key Informant Interviews (KIIs) for data collections. The collected data was analysed through the inductive Thematic Content Analysis (TCA). Major study finding reveals that the relevant stakeholders, including the local South African Police Service Stock Theft Unit (SAPS STU), livestock farmers and other Anti-Stock theft structures were knowledgeable about DNA technology. However, the finding indicates that they faced various difficulties in terms of proper application of this technology. As a result, far-reaching multiple effects were strongly highlighted, as the three identified study themes of this study refers. Improvements have to be made with regard to the use of DNA technology, as one of the current strategies to combat this scourge in the selected areas of KZN Province. This calls for the induction of DNA technology through training of communities, marking livestock, improving socio-economic conditions, practicing livestock documentations, implementing legislative frameworks, regulations and trading patterns, as well as enhancing Criminal Justice System (CJS) responses. The selected participants shared some positive anecdotes to combat this crime, however, there is still more to be done to win the war of stock theft in the selected study locations.

Keywords: Effectiveness, factors, combating, deoxyribonucleic acid, hindering, KwaZulu-Natal province, progress

1. INTRODUCTION

Stock theft is prevalent in all provinces of South Africa. It is also a problem globally, with more complexities compared to other property-related crimes. Livestock theft have negative consequences on the farming communities. These are not only financial, but can also be physical, such as injuries and killings of livestock owners, and psychological or emotional to both the actual and potential victims (Doorewaard, 2015a, 2015b). According to SAPS (2011:2 & 7) and Stock Theft Act (No. 57 of 1957); 'stock' refers to:

“Any horse, mule, ass, bull, cow, ox, heifer, calf, sheep, goat, pig, poultry, domesticated ostrich, domesticated game, or the carcass, or portion of the carcass of any such stock, while the definition of ‘animal/livestock [Domesticated] produce’ means whole, or any part of, skins, hides, horns, intestines, heads, parts of bones, claws, semen, or embryos, and any wool, mohair, or ostrich feathers, and ostrich eggs.”

Rural livestock farmers, farm workers, and residents within rural communities, are considered vulnerable soft targets by stock thieves. This is because of their isolation geographically, the remoteness and vastness of their areas, high market value placed on livestock, distances between livestock farms, police stations and villages, transportation accessibility, and lack of basic infrastructure, like roads (Maluleke, 2014). This scourge of stock theft is nothing new to livestock farmers from a South African perspective. The available research (Clack, 2013; Doorewaard, 2020; Lombard, 2015; Lombard, Van Niekerk & Maré, 2017; Lombard, van Niekerk, Geyer & Jordaan, 2017; KZN Department of Community Safety and Liaison - KZN DCSL, 2008; Maluleke, 2014; Maluleke, 2016; and Manganyi, Maluleke & Shandu, 2018) contend that stock theft is as old as agriculture itself. The recorded cases of stock theft in South Africa can be traced as far back as 1806. Livestock theft has become a lucrative business in South Africa and affects the livestock industries in all nine provinces in the country (Maluleke, 2014; Maluleke, 2016; Maluleke, 2018; Maluleke & Mofokeng, 2018). The selected areas in KZN Province (Bulwer, Ladysmith and Utrecht) are prone to stock theft, which causes long-term pain and suffering to the livestock farmers. The KZN Department of Community Safety and Liaison [DCSL] (2008) observes that different crimes occur on farms in general, and form an integral part of South African history. From the mid-1990s, the old cycle of theft and counter-theft [Stock theft included] has been witnessed. Its integration into rural communal life is recorded, and it shows high levels of occurrence.

The notable changes in livestock prices have reportedly led to high numbers of reported stock theft cases across South African rural areas. Thus, the researcher submits that the current strategies of dealing with this problem are ineffective, and this leads to serious financial and personal losses to the local livestock farmers. Peires (1994:2) highlights that this crime is still regarded as an African crime, and forms art of rural criminality. There is a scarcity of research that analyses the nature, extent and implications of stock theft. Even less research has been done to elucidate the nature of organised crime in the black rural areas, where the targets are not ethnic strangers but one’s neighbours and relatives (Peires, 1994:2). Clack (2013:77) highlights that the agricultural sector is one of the cornerstones of South African’s economy. Thus, crimes occurring in rural agricultural communities should be researched, in order to clearly understand the economic impact and challenges on food security.

This study field is often neglected by researchers in the Criminal Justice disciplines, such as Rural Criminologists/Criminologists. These disciplines could contribute significantly to the body of knowledge on this subject. Such knowledge is critical to identify gaps in, and offer adequate analysis of this crime. This study aims to present knowledge on the use of DNA technology in the combating of stock theft in the selected areas of KZN Province, and to explore the factors that hinder progress and effectiveness of current strategies that are implemented to combat this crime.

While considering the submissions made in this introductory section, the factors hindering progress and effectiveness of using DNA technology to combat stock theft in the selected areas of

KZN Province was the objective of this study. Therefore, it is hoped that the findings of this study will fill the gaps, as well as address the inconsistencies and existing controversies in the existing body of knowledge. The basis of the study rests on DNA technology applications to combat stock theft in the selected areas of KZN Province. Ladysmith, Bulwer (Pietermaritzburg) and Utrecht (Newcastle) were chosen. The participants in this research included the KZN Department of Agriculture, Forestry and Fisheries (DAFF) officials, SAPS STUs officials, SAPS STU Provincial Coordinator, livestock farmers, managers of Anti-Stock Theft Associations, and Community Policing Forums (CPFs) leaders. All the participants participated in the FGDs and KIIs. The reviewed literature/documentary studies were matched with participants' verbatim expressions to the identified three study themes.

2. LITERATURE REVIEW

This section presents the body of literature to assist in the exploration factors hindering progress and effectiveness of using DNA to combat stock theft in the selected areas of KZN Province. The problem formulations and nature of this crime is discussed in detail, as well as the value of DNA technology in this regard. The key areas in combating and policing stock theft also form part of this section.

2.1 Exposition the nature of stock theft and the determination of the value of Deoxyribonucleic Acid to combat stock theft

Mapholi (2015) contends that stock theft remains one of the major challenges to the livestock farming community across South Africa. It impacts the economy of many sectors; from large commercial organisations, to the stud breeders, and the rural livestock farmers owning one or two herds of cattle. The African News Agency [ANA] (2021) reports that stock theft is costing the South African economy about R1.4 billion annually. In 2020/2021, the value of stolen cattle was over R779 million, with the value of R862 million for the 2019/2020 financial year. The Anti-Stock theft authorities recovered stolen cattle valued at more than R210,6 million, compared to R251,2 million in 2019/2020. The value of stolen sheep amounted to almost R212 million for 2020/2021, with R206 million for 2019/2020 recorded. Losses suffered due to the theft of goats were just over R116,8 million in 2020/2021, while the losses amounted to almost R111,4 million in 2019/2020 (Marais, 2021).

As a result of the findings above, the local SAPS identified this crime as one of priority areas by establishing partnership between them and the Animal Genetics Laboratory (AGL) of the Animal Research Council (ARC), and the Animal Production Institute (API) at Irene, Pretoria in 1996. This was initiated to address stock theft challenges by applying DNA technology. From this agreement, about 45 000 cases of stock theft were reported, with only 8 000 reported cases going to court. More than 500 of these court cases, involved more than 3 000 exhibits that relied on DNA analysis. About 95% of these cases were resolved, accomplishing suspect prosecutions. The accompanying four tables illustrate the economic impacts of stock theft and the estimated value of livestock stolen and recovered per year.

Source: Clack (2021) and Mabunda, Maluleke and Barkhuizen (2021)

In an attempt to understand factors hindering progress and effectiveness of using DNA technology to combat stock theft in the selected areas of KZN Province, Kempen (2015:10) confirms that DNA can be best used to link potential stock thieves or suspects to stock theft scenes. With the use

of DNA, criminals can be identified with incredible accuracy, owing to biological evidence. Moreover, they can also be cleared or exonerated if mistakenly accused or convicted. This technology is pivotal in ensuring accuracy and fairness in the CJS. However, over reliance on the traditional methods of physical matching of animal hides, bones and ivory with animal identification tools, such as brand marking and tattooing, as well as placing more emphasis on current legislative frameworks, like the Stock Theft Act (No. 57 of 1959) and Animal Identification Act (No. 6 of 2002) is not helping the current status of effectively combating this crime. The envisaged integration of the conventional methods with the ‘DNA technology’ is largely ignored in and the selected areas of KZN Province, and in South Africa, in particular.

This study identified the factors hindering progress and effectiveness of using DNA technology to combat stock theft, to provide notable contribution to the safety measures, preservations and protections of livestock, South African economies and the local livestock farmers. This was proposed by soliciting experiences of various prominent Anti-Stock theft associations to explore current stock theft combating strategies by means of available literature studies and operations, and empirical findings. The crux of the discussions in this study revolved around functions of combating this crime by using DNA technology, while considering the existing hindrances. Stemming from the findings of this study, recommendations will be made for future improvements and intervention systems by explaining the value of DNA technology in combating stock theft. This can also be used to highlight vast experiences in conducting research, guided by the applications of DNA technology and combating of stock theft. To this end, courses and educational materials can be developed, or designed interventions can be implemented to assist relevant Anti-Stock theft structures with the provision of adequate services and informing of policies related to the improvements of the livestock farming sector.

Through the application of DNA technology to combat stock theft, the livestock acts as the ‘reference sample.’ Van der Walt (2015:196) states that “reference samples are used in the process involving disputed samples, which can be compared to the evidence collected from the stock theft scenes. This sample is regarded as ‘origin,’ because it can be used to identify the origin of the disputed sample. For the purpose of this study, the researcher contends that ‘hair’ found at stock theft scenes can be collected as evidence (i.e., a disputed sample). It can then be compared to the livestock ‘hair’, or another known livestock. To this end, a reference sample which is deemed to have some form of relationship can be linked to the stock theft scenes through the verifications of collected samples, and a DNA profile can be built. This can act as the representative portion of a known sample. For practicality, the collected samples are kept in a file or in the laboratory, as typical reference of livestock, to avoid transient evidence, such as the ‘hair, blood, and intestines,’ to name only three, to become degraded nor contaminated, this evidence is swiftly collected to avoid losing its value. Essentially, the use of standard samples obtained from the laboratory for a possible comparison of evidence similar to the known sample, such as sources of DNA [Carcasses; Vehicles; Firearms; Blood/Bloodstains, Hair, Meat or other tissues; Fingerprints; Footprints; Equipments used during stock theft; and Clothes], found in a stock theft scene, cannot be accomplished without the use of the reference samples in the laboratory, NSTPF (2016:32).

Research conducted in the KZN Province by the KZN DCSL (2008) indicates that the challenges on policing stock theft can be restricted to the following aspects: 1) Many livestock owners, 2) Individuals entrusted to take care of the livestock, including herdsman or family members;

normally report stock theft incidences to the local SAPS STUs far too late or choose not to report it at all. Therefore, based on inadequate monitoring and counting of livestock, they often realise too that their livestock is missing. They also search for their stolen livestock first before reporting their alleged cases [i.e., late/delay reporting]. This can be influenced by travelling distances to the main city adjacent to the selected rural areas (KZN DCSL, 2008:17). The researcher noted uncontrollable organised nature of this crime is currently existing in South African rural communities. Chelin (2019), Dean (2020); and The Economist (2020) agree that the threat of growing transnational organised crime involving stock theft is posed by syndicates who steal cattle in South Africa, taking them across the border to Lesotho for a cooling-off period, and then selling them back to South Africans.

2.2 Key areas in combating and policing stock theft

The KZN DCSL (2008:17 & 18) went on to suggest the following areas requiring more attention when policing stock theft in the KZN Province holistically:

- The SAPS STUs make use of livestock pounds for safekeeping during criminal trials or until the owner is positively traced. Therefore, adequate provisions of such pounds and payable fees should be reviewed.
- The local ‘Municipal pound’ in Vryheid, charge a fee of R50 per day, which is significantly higher than at nearby private pounds, like the ‘*Nooitgedacht*,’ which charges R8 a day. Thus, lack of adequate impounding facilities complicates the confiscation of livestock from the stock thieves. Importantly, the proposed National Animal Pounds Bill [Notice 398 of 2013] should be put into practice.
- Swaziland authorities are reportedly not reporting South African cattle found in their country, while the local SAPS STUs make efforts to notify Swaziland authorities if cattle from Swaziland are discovered in South Africa.
- Witnesses are not always traceable. In some cases, they refuse to cooperate, due to intimidations by stock thieves.
- Forensic investigations often take long, for example up to six (06) months.
- Stock thieves compensate victims, who then withdraw cases and become uncooperative towards the SAPS STUs investigating officers.
- Complainants enter into compensation agreements with stock thieves and only report the matter to the police if their agreement is breached.
- Traditional leaders, affectionately known as *Amakhosi*, sometimes mediate stock theft cases informally with the communal level, and some of these cases are not reported to the local SAPS STUs due to the increasing lack of trust and confidence between them.
- Delays in reporting of stock theft cases makes investigation difficult (KZN DCSL, 2008:17 & 18).

Limited studies have been done to explore factors hindering progress and effectiveness of using DNA technology to combat stock theft in the selected areas of KZN Province and other South African provinces. However, it is established that this technology is not effectively used to combat this crime in the selected areas within the identified province. The limited use of Criminal Law (Forensic Procedures) Amendment Act (No. 37 of 2013) (the ‘DNA Act’) is witnessed, while it is proven as an effective remedy for combating this scourge by providing rapid livestock

identification, as a confirmatory forensic tool to be used in the criminal and civil stock theft cases. Negatively, the majority of participants had limited knowledge regarding DNA technology to combat stock theft (Maluleke & Mofokeng, 2018).

Maluleke (2016) further highlights those studies on stock theft focused only on traditional methods to combat, prevent and investigate stock theft. Limited studies have been done on the application of DNA technology to combat stock theft in the KZN Province and other provinces of South Africa, and on the factors hindering its progress and effectiveness thereof. Researchers in the 'property-rated crimes' study field did not give stock theft related research required attention in South Africa. This crime is regarded as a minor crime in the public eye. Considerably, DNA technology is designed to revolutionise modern science to combat stock theft amongst other crimes in the country. As this crime evolves, more technological applications should be discovered to help in understanding its nature and its prevention. This technology provides irrefutable means of livestock identifications, focusing on unique livestock DNA profile. When livestock gets stolen, illegally relocated or even slaughtered, livestock biological samples can be taken, to compare their DNA profiles to the reference samples. This can be used to verify their identities and possibly link stock thieves to the stock theft scenes. This technological application can identify stock thieves with accuracy when livestock biological evidence exists, as initially stated (Maluleke, 2016). The value of using DNA technology in combating stock theft was not clear to most of the study participants. They focus on using traditional methods, such as brand-marking and tattooing, while placing more emphasis on legislative frameworks, such as the Stock Theft Act, 1959 and Animal Identification Act, 2002, respectively. As initially revealed, this is practiced while invalidating the use of the DNA Act, 2013 (Maluleke, 2016).

Memon, Kumar, Memon, Chowdhry, Aamir and Kumar (2016:1) contend that this crime has been a problem in the agricultural sector globally, regionally, and in South African rural areas, and it is reportedly threatening both commercial and emerging farming sectors. This crime can be emotional, psychological and financial-economical in nature, and its full impact is not yet realised. Most livestock farmers seem to be apathetic towards this problem, only reacting when stock thieves steal from them. Most of the SAPS STUs operations and patrol operations focus on organised runners responsible for stealing livestock and the local livestock farmers and the SAPS STUs channelling their energies, time and resources to combat stock theft unsuccessfully. Thus, an urgent change on latest strategies is required, to closely look at the extent, organised syndicate *MO* and identified outlets of stolen livestock. More than 131 000 stock theft [i.e., stolen livestock] reported cases are recorded yearly. The Free State Province alone registered about 4 000 cases. Equally, majority of stock theft cases are not reported, as the local livestock farmers feel that nothing will be done with their reported cases. This results in thousands of similar cases not being recorded in the official SAPS stock theft statistics (Harvest South Africa, 2021).

The Statistics South Africa (Stats SA) reveals that non-reporting of stock theft cases is approximately 70.7%. It is also estimated that the value of stolen livestock during the 2019/2020 was around R1 179 458 600. On average, there were about 182 cattle, 282 sheep and 138 goats stolen every day in South Africa (Harvest South Africa, 2021). The unchecked stock theft incidences are quickly becoming one of the gravest challenges to the South African livestock farmers, as they normalise waking up daily to find hundreds of livestock, like cattle, sheep or goats stolen. This adds to other devastating challenges they face, such as the farm attacks, droughts, and

constant threats of farms expropriations, with zero compensation. Between July and September 2020, there were 7 339 cases of stock theft across South Africa, recording over 26 300 sheep and 14 000 cattle stolen (Democratic Alliance – DA, 2021).

For remedy, Kempen (2015:10) contends that the DNA technology can positively link potential stock thieves to the identified scenes with incredible accuracy, and the livestock biological evidence makes this process possible. Stock theft suspects can also be cleared and exonerate if mistakenly accused or convicted of crime, as previously indicated. The CJS can also benefit from this technology by offering fair justice practices. The CJS should use this technological application as one of the important forensic instruments to combat this crime. The DNA-based technologies can be effectively used for livestock determination of identity, ownership, percentage, traceability and the species origin of animal products, such as tissue, blood and skin. Apart from identical twins or clones, no two livestock are genetically the same (NSTPF, 2016:34). Therefore, this study views livestock DNA as a fingerprints or unique identification. Importantly, only small quantities of this technology is needed to confirm livestock fingerprints. This technology can efficiently help to combat stock theft in South African rural areas through the application of the following processes:

“Hair samples (i.e., a source of DNA) are collected from individual livestock and stored in the laboratory as reference samples. When a livestock gets injured or have been slaughtered at a stock theft scene, or a piece of meat from a stolen livestock is found in possession of a suspect, a tissue sample is taken and compared to the reference sample in the laboratory. If the DNA fingerprint of the reference samples matches a sample from the stock theft scenes, the potential stock theft suspect can be linked with the identified scenes or committed stock theft itself, and the collected evidence can be used to put a potential offender behind bars. In other cases; even if there is no reference sample available, conviction is still possible if a DNA from blood/bloodstains, meat or other tissues found at the stock theft scenes compares with blood found on the stock theft suspects’ clothes, tools that were used, or meat found in his/her possession,” (NSTPF, 2016:35).

Lochner and Zinn (2015:34 & 35) highlights that a crime scene can generally and naturally be classified into five types, namely: 1) *Primary crime scene*: referring to a location detailing immediate vicinity of crime occurrence or incident and where majority of physical evidence can be obtained, proving elements of the identified crime under investigation are possible found, stock theft in this regard). 2) *Secondary crime scene*: This refers to a specific location, which may not be in the same vicinity as the primary crime scenes, but a distance from the primary scenes. 3) *Extended crime scene* relates to a crime scene where several unlawful actions occur, at different places while an offence is being committed. 4) *Macroscopic crime scene*: This is demarcated to the classification of a crime scene based on its size. It is not just a physical scene but can also include livestock carcasses. 5) *Microscopic crime scene* refers to any small or minute object or piece of physical evidence related to the case under investigations. According to Maluleke, Mokwena and Olofinbiyi (2019:110), the typical stock theft scenes can be found outdoor, indoor and mobile. Accordingly, and this can be divided as follows:

- The livestock may be found at the location where they were slaughtered (Outdoor and indoor scenes).

- The livestock may be slaughtered in a specific location to be transported by a suspect to another location for selling (Mobile scenes).
- The livestock may be stolen and moved to another location and to another owner for further illegal rearing, which may later be discovered (Mobile scenes).

Therefore, the success of the forensic DNA technology services is dependent on relevant parties involved to correctly collect required samples at stock theft scenes, process and analyse them in the laboratory, and report the findings. To ensure that each part of the process is handled correctly, the ARC continuously provides training to the SAPS STUs staff, covering DNA sampling, preservation, documentation, and dispatching of samples to the laboratory (NSTPF, 2016:35).

3. MATERIALS AND METHOD

This qualitative study was exploratory in nature, supported by the FGDs, KIIs and documentary studies for data collections. It was confined to the selected areas of KZN Province (Ladysmith, Bulwer - Pietermaritzburg and Utrecht - Newcastle). The non-probability, purposive sampling was adopted to select certain categories of participants, which provided more detailed information on this subject. Their years of experience as part of Anti-Stock theft structures were considered. The 57 selected participants comprised Black and White South Africans who speak English and IsiZulu, fluently.

The participants were distributed as follows: two DAFF staff [Assistant Directors: Animal Technicians and Animal Production officials] (KIIs); one SAPS STU provincial co-ordinator (KII); thirty-eight KZN SAPS STUs members (fourteen by means of KIIs, and 24 were part of the FGD); eight livestock farmers (FGDs); three CPF managers (KIIs); and five Anti-Stock Theft Association managers (KIIs), Manganyi, Maluleke and Shandu (2018). During the record-taking process; the researcher took notes and wrote detailed and complete report afterwards. A voice recorder was also used for conducting the FGDs and KIIs, and for performing transcriptions at a later stage.

The collected data was organised by categorising it according to the identified three study themes, while applying the inductive TCA. This was done by identifying similar features. It was ensured that the obtained empirical data and reviewed literature studies answered the objective of this study. The collected data was contextualised in a rich and descriptive manner, focusing on the use of DNA technology and stock theft combating strategies through the development of a conceptual framework in this regard. The researcher read the gathered data several times to grasp the selected participants' perceptions in comparison to the reviewed studies on this subject. This was done by making cryptic written notes of what the participants were saying during the FGDs and KIIs to elicit the identified three study themes. The actual words used by the participants were written down verbatim (Matlala, 2012: 113 & 114) and Maluleke (2016).

4. IDENTIFIED STUDY THEMES AND DISCUSSIONS

When the selected participants were asked about factors hindering the effectiveness of using DNA technology to combat stock theft in their selected areas, they shared the following in verbatim, this was followed by discussions on each study theme. Importantly, the following three study themes were identified during the interview process. Empirically, the referencing method for the interviews in this study comprised a numerical sequence. An example of this notation is as follows:

(5:1:2). The first digit (5) refers to the folder number in the voice recorder. The second digit (1) is the interview number in the aforementioned folder, whilst the third digit (2) is the sequence in which the cited interview was conducted, based on the FGDs and KIIs.

4.1 Limited prioritisation of stock theft scourge

“Some of our local courts do not consider stock theft as priority crime, even when they give convictions, they normally give three (3) months or suspend the sentence. It is very important to understand the value of livestock for African people as it is their back, their money” (FGDs-04:16:6).

“The current system does not comply with the systems of the traditional leaders; they can oppose anything with everything (might) that is the reason why we cannot have these improvements. There are more challenges to be precise” (KII-01:01:01)

“Quite few of our cases has been stricken off the roll because of the fact that we wait longer time for the financial authority process to be finalised and still have to send the DNA evidence away and wait for another 03 to Four (04) weeks for the feedback from the laboratory (for the results to come back). In that period of time the court refuses to remind the dockets Two (02) and Three (03) times and just strike off the roll and by that time you receive positive results then you have another problem you struggle your backside to go and find the accused as he / she is given bail or out and running away and struggle to locate that accused, that is also a big challenge that we have” (FGDs-04:16:6)

From the presented verbal expressions, this study shows that this crime is not regarded as a priority crime in South Africa. The selected participants contend that stock theft should be seen as one of the ‘National Priority Offences,’ requiring National government, SAPS STUs and other relevant stakeholders needed attention, in terms of combating, prevention and investigation. This crime should be viewed as a specialised field, with Section 16(1) of the SAPS Act, 1995 guiding this process. The Minister of Police should also intervene by offering new strategies, supported by the National Joint Operational and Intelligence Structure (NATJOINTS) within the provincial boundaries. The local SAPS, South African National Defence Force [SANDF], should clearly focus on border security, while applying intelligence-led policing, together with the National Intelligence Agency (NIA). In essence, stock theft should be urgently prioritised.

4.2 The finalisation of the DNA evidence feedback delayed from the laboratories

“While noting the importance of DNA technology in combating stock theft, they are issues that come upfront, like for instance, we had an issue the other day when one of our members received DNA results samples back from ARC-Irene and I really do not know what happened there but the case numbers did not correspond with the cases numbers as sent to Irene when it come back, it was completely difference and the results received did not make sense. So, we had to send back these results and make a query about it and then after that they eventual send back the results with correct case numbers but incidences of this kind do not happen a lot” (FGDs-04:16:8)

“Communal grazing lands, in that one bull may mate with several cows of different livestock owners over a period of time. When animals are stolen, one will for example find DNA of both parents in the off spring. Little knowledge of Livestock Identification Catalogue (LIDCAT) utilisation within the livestock owner Community. What is LIDCAT? - Build secure database for animal identification system, collecting biological materials from individual animals and storing

it under ideal condition. In the case of theft or dispute, the system can be used to identify the animal beyond doubt for court purposes and build a database for research purposes” (KII-06-01-01).

“We have got another case where I took human DNA using buccal swab evidence method – taken from the suspect’s mouth and have Touch-DNA from the recovered firearm to send to Cape Town laboratory. It is Five (05) / Six (06) months in and we were told that it can take-up to a year for them to send the results back. Touch-DNA can directly connect the suspects to the crime scene if found and proven positive, it is like fingerprints. We sent the samples and now we do not know which suspect(s) handled the firearm. Only if we can have a method of making these processes quicker, not a method of ‘hurry-up-and-wait.’ It should be noted that human DNA evidence results take very long to come back, sometimes it can take-up to Six (6) - Seven (7) months” (FGDs-04:16:5)

“The feedback from the laboratory takes long ... In a criminal case it can take up to Six (6) weeks and sometimes Three (3) months, the deadline is not adhered to, and this create problems with the court of law as stock theft cases get reminded, but is good to note that they are improving now, it is bit better but it is a big challenge for us to get the DNA reports quickly” (KII-5:1:1)

From the foregoing responses, it is evident that there is an urgent need for the establishments of the advised Stock Theft Forensic Laboratory (STFL) in the selected areas of KZN Province to avoid travelling long distances to submit DNA evidence obtained from the stock theft scenes. Currently (2022), Cape Town, Port Elizabeth and Pretoria, only have laboratories to analyse the high demands stock theft DNA evidence. Positively, the University of Pretoria (UP), ARC-Irene and other relevant private companies are acknowledged for offering quick feedback responses, based on the awaiting livestock DNA results.

4.3 Inadequate knowledge and application of the DNA technology usage

“These refer to the experienced challenges among others:

- *Lack in community involvement in some areas;*
- *Late detection and reporting of cases to the SAPS STUs by livestock owners;*
- *Non-marking of livestock by owners;*
- *Improper or non-safeguarding of livestock by owners;*
- *In-effective actions by livestock owners themselves to prevent stealing of their stock;*
- *Porous International borders (Lesotho, Swaziland and Mozambique), however, cross-border stock theft in KZN Province is very low in comparison to the total stock theft picture of the province; and*
- *Filling of vacancies at remote SAPS STUs” (KII-06-01-01)*

These included the following that arose from similar challenges experienced by the selected participants (Not in order of importance):

- The local livestock farmers should look after livestock.
- They livestock farmers embrace the importance of the Stock Theft Act, 1959, Animal Identification Act, 2002 and the DNA Act, 2013 to name just three.
- The livestock farmers should frequently count their livestock to avoid discovering that their animals are missing only after a few days, or two to three months, making the investigation process difficult to initiate and complete.
- The livestock farmers should report stock theft cases immediately.

- The majority of local commercial livestock farmers, more especially ‘White’ commercial livestock farmers use other technologies, such as the Radio Frequency Identification (RFID) to control and monitor their livestock’s movements within their enclosed facilities. This system can be very expensive for emerging ‘African/Black’ livestock farmers. Positively, the optional combination of the RFID, Wireless Fidelity (Wi-Fi), Wireless Sensor Node / Network (WSN) and ZigBee can ease the noted economic burdens.

In instances where a stock theft case cannot be proven due to lack of *prima facie* evidence, this technology can positively link potential stock theft suspects to the identified scenes, solving this crime with much ease. However, there are no plans to establish the STFL in the province, further making it difficult to deal with this crime in the selected areas of KZN Province. The existing knowledge and applications of this technology should be enhanced at all costs.

Overall, the researcher is of the view that the findings of this study can prompt readers to think of other contexts, settings or situations facing similar problem across South Africa and elsewhere, and to recognise the similarities. This study did not involve broad claims, but invites study readers to make connections between elements associated with the study participants in line with their own experiences. Thus, the researcher explored the subject relating to the factors hindering the progress and effectiveness of using DNA technology to combat stock theft in selected areas of KZN Province, while giving rich description of this study subject so that the study findings can be applied to other settings in order to contribute to the building of a new and technological pool of knowledge in respect of combating stock theft in the selected areas of KZN Province and elsewhere.

Overall, the use of DNA technology for combating stock theft seems to be a new concept to the livestock farmers residing in the selected areas of KZN Province. This can be also said about other relevant stakeholders, such as the CPFs leaders and DAFF personals. Another development is that local SAPS STUs officials and Anti-Stock theft associations are knowledgeable about this technology. However, the interviewed participants noted that they faced various difficulties associated with stock theft, and many factors are available hindering this process. Thus, improvements should be made regarding current stock theft combating, prevention and investigation strategies within the selected areas of KZN Provinces, more still to be done to combat stock theft effectively in this province to respond to a decline in the willingness of combating, preventing and investigating this scourge by relevant Anti-Stock theft structures.

5. CONCLUSIONS AND RECOMMENDATIONS

This study concludes that the use of DNA technology in combating stock theft in the selected areas of KZN Province can be very effective. However, the effectiveness of this application has not been clearly identified in the study locations, as differed perceptions were shared. Many factors exists that hinder progress and effectiveness of this technology. Thus, this technology should be fully explored to efficiently address this crime effectively. For recommendations, the prioritisation of this crime should be urgently addressed by all Anti-Stock theft structures, the finalisation of DNA evidence analysis, coupled with the establishment of the STFL in the province and the proper applications and scientifically disseminations of available knowledge should form part of this agenda. This technology can be one of the solutions to combat, prevent and investigate this scourge. The livestock ownership, both in civil and criminal cases can be achieved, by linking

potential stock theft suspects to the identified scenes, as well as exonerating innocent stock thieves. The livestock DNA is regarded as the ‘fingerprint’ and DNA collected from stock theft scenes that can either link stock theft suspects to the obtained evidence or eliminate them and compare the obtained evidence from one stock theft scene to others can enable potential stock thieves to be linked Nationwide, to provide valuable criminal [stock thieves] intelligence information to the local SAPS STUs and act as evidence in a court of law.

Importantly, the researcher further recommends that the SAPS management should give this crime the necessary public exposure. The South African CJS should start taking this crime seriously. All Anti-Stock theft structures should undergo in-depth constant lectures, workshops and quarterly refresher courses regarding the importance of livestock farming practices and consequences of stock theft. The National government should also initiate relationships with other relevant forensic laboratories across the country. Specific National Instruction should be added to the Crime Scene Policy (CSP), containing full descriptions of how to use this technology for combating, preventing and investigating this crime, as well as stock theft expert requirements. Over reliance on the ARC-Irene will not effectively combat stock theft, based on witnessed workload. The University of Stellenbosch in Cape Town and the UP are some examples of the notable forensic laboratories, which can add much value by their speedy analysis of DNA evidence. Other private laboratories should also become part of this solution. The SAPS management should also consider having their own STFL.

Moreover, it was clear, from the participants’ perspective, that knowledge of the application of this technology was limited. It is further recommended that more SAPS STUs’ members should be trained specifically in the usage of this technology. It would be best if each SAPS STUs in the selected areas of KZN Province could have designated DNA technology experts working along with the respective forensic laboratories across the country or the advised STFL. This can assist the SAPS STUs with investigations of this crime. This technology has proven to be a solution to the stock theft epidemic by providing rapid means of identification. It can be used as a confirmatory forensic tool in livestock identifications, irrespective of either criminal or civil nature.

THE INFLUENCE OF THE AfCFTA CAPITAL AND INDUSTRIAL GOODS IN SOUTH AFRICA: A SIMULATION ANALYSIS.

M.T. Pasara

North-West University, Vanderbijlpark, South Africa

S.H. Dunga

North-West University, Vanderbijlpark, South Africa

ABSTRACT

South Africa is already faced with macro-challenges of suppressed economic growth, increasing unemployment and inequality levels on one end. On the other end, the unavoidable pressures and priorities of regionalism and globalisation such as the African Continental Free Trade Agreement (AfCFTA) continue to increase. General trade theory postulates for positive gains between trade openness and economic growth. However, these generalisations often distort critical sectoral implications due to trade creation and trade diversion effects. This paper aims to answer the potential effects of the highly celebrated AfCFTA on the Fourth Industrial Revolution (4IR) in South Africa. This is achieved by applying the WITS-SMART simulation model on three key Harmonised Commodity Description System (HS) Classifications of capital goods and industrial goods by estimating the trade creation, trade diversion and revenue effects. Secondly, the potential dynamic effects on macroeconomic fundamentals of economic growth and unemployment are also estimated. Results indicated that for the two product classifications of industrial and capital goods, applied duty rate will slightly decline from 6.83 to 6.39 whilst the weighted rate will increase by 2.86%. Consequently, there will be an increase in South African exports by approximately USD 121 million but no changes were observed for imports. This is because it is likely that South Africa will not import any industrial and capital goods from any African country even though the AfCFTA is to be implemented due to capacity constraints. Lastly, results indicated that no significant effect will be observed in terms of trade creation and trade diversion leaving welfare effects and consumer surplus unchanged in the two product categorisations. The study recommends that South African policy makers should not only implement the AfCFTA but also proffer complementary policies which seek to exploit the increased market access of the three HS product categories. This is feasible given the comparative advantages South Africa has in the region on the production of the aforementioned products. However, this may not be as significant in the short and medium term due to lower absorption capacity in the region.

Keywords: South Africa, AfCFTA, 4IR, WITS-SMART simulation, economic integration, trade creation, trade diversion

INTRODUCTION

Irrespective of several international trade models which posit that trade openness leads to economic growth (Smith, 1776; Ricardo, 1817, Irwin, 1996), governments have not always been keen to open up their economies for several reasons. Among others, these include a subconscious belief in protectionism by policy makers in mercantilist ideologies which are largely rooted in the notion of zero-sum game (Gurova, 2014; Musila, 2005, Irwin, 1996). Others reasonably also cite

that the need to protect local and infant industries from predators which are usually multinational corporations which usually employ unfair trading practices to thwart out any form of competition. Despite some arguing for multinationals citing that they usually contribute to high employment rates in their operational economy, another school also argue that these multinationals do not contribute much to growth since much of the revenue and profit is withdrawn from the domestic economy to the parent country. Using Keynes' rationale, withdrawals are outflows and not good for growth due to the negative multiplier (Keynes, 1936). Thus, in practice, the subject of international trade and trade openness has not always been a cut and stone one. This paper intent to discuss on the potential merits (and demerits) of the recently signed African Continental Free Trade Agreement (AfCFTA) on the South African economy by focusing on three product classifications namely capital goods, industrial goods and petroleum. The paper will follow the Harmonised Commodity Description System (HS) which is internationally recognised and adopted by various international trade institutions including the International Trade Center (ITC) and UNCTAD. The AfCFTA arrangement is coming at a point when South Africa is pursuing other key policy issues - such as the Fourth Industrial Revolution (4IR). It will be of interest to analyse whether the new AfCFTA development plays a complementary or contrasting role to these growth-oriented policies such as the 4IR. Various contrasting theories posit varying arguments from the need for protectionism to the merits of trade liberalisation as intended by the AfCFTA instruments.

The 4IR was considered by many as a major disruptor to the South African economy. This is because while others posit that it will lead to increased productivity and production due to the use of advanced technologies thereby increasing economic growth (Mill, 1920; Cataneo, 2005, Karambakuwa et al. 2015), others have also highlighted that the 4IR could significantly compound to the already existing macroeconomic woes of high unemployment rate in South Africa. The rate of unemployment in South Africa has been worsening over the past decades and latest statistics indicates that the indicator hit a new record high of 34.9% (StatsSA 2021: Q3) from 34.4% (2021:2). If discouraged jobseekers are to be taken into account, the rates become even higher to respective figures of 46.6% and 46.2%. Prospects for the future become even gloomy bearing in mind that the level of youth unemployment is highest with a 2021: Q3 figure of 66.5% (StatsSA: Q3). In the preceding years, unemployment figures have been as follows: 26.54% (2016), 27.04% (2017), 26.91% (2018), 28.47% (2019) and 28.74% (2020). This reflects that unemployment has been on an upward trajectory for a couple of years with the coronavirus pandemic only compounding to already cause existing challenges. From a theoretical perspective, one could attribute this phenomenon to the inverse relationship between inflation and unemployment widely popularised in the Philips curve since inflation has remained low in the past two decades.

However, other factors could also significantly contribute to this structural outcome in South Africa. This paper will place its focus on the role of trade openness with a specific focus on the AfCFTA. South Africa being arguably one of the largest economies in Africa, and the largest in Southern Africa implies that its role on both international trade and intra-African trade will be significant. It remains critical that at every stage and new development such as the AfCFTA, a critical analysis be made to assess how such changes can influence the dynamics within the South African economy. This paper seeks to provide some critical insights into the influence of intra-African trade as proposed by the AfCFTA instruments on the 4IR and the South African economy in general.

This paper is structured as follows; the subsequent section discusses the theoretical and empirical literature. This is followed by the methodology section and then a discussion of results. The conclusion and recommendations are then suggested drawing from a blend of the theoretical, empirical and estimated results.

THEORETICAL AND EMPIRICAL PERSPECTIVES

The convergence arguments by Robert Mundell (1965, 73) posit that it is through macroeconomic convergence that economies can grow as they will be able to benefit from each other. Using the ex-ante argument, the model posits that there are pre-conditions which should be made before economies can successfully integrate with each other. These include ensuring that economies are synchronised, that is, macroeconomic indicators are moving within a systematic fashion. Prior to the signing of the AfCFTA, there existed macroeconomic convergence criteria within various regional economic communities (RECs) including the Southern African Development Community (SADC) (Pasara and Dunga, 2019b). The notion behind was to ensure that there is fiscal and monetary discipline and economies would move in a systematic fashion. This would be key from two strands: firstly, similar policies can be effectively applied at the REC level in the case of external shocks. When economies are not synchronised or there is no ex-ante convergence, then corrective policies will become effective in one economy and ineffective in another. For instance, it was lack of proper macroeconomic convergence which led to varying results across SADC countries during the 2008 Global Financial Crisis. In countries like Zimbabwe, the shock became so severe that the economy was grounded whilst mild shocks were experienced in neighbouring countries like South Africa and Botswana. The consequence was negative spill over effects from Zimbabwe to South Africa since there already existed some level of economic and/or trade integration between the two economies.

The ex-ante convergence argument then becomes critical in the context of larger trade integration arrangements such as the AfCFTA. There is sufficient empirical evidence to indicate that no effort was done to ensure that some form of convergence exists among African countries before the AfCFTA can be ratified and implemented. Unlike the European Union, Africa is a continent of extremes. On one hand, there are highly stable countries like Mauritius and Botswana and very unstable economies like Zimbabwe, Nigeria and Ethiopia on the other. There are larger economies like Egypt, South Africa, Kenya and Nigeria and smaller economies like Malawi, Sierra Leone, Gambia and Lesotho. All these disparities have trade implications. In the case of South Africa, trade openness in the context of AfCFTA would imply that negative shocks can easily spill over from trading partners such as Zimbabwe since there will be little to no trade barriers.

The ex-post convergence argument views to the contrary. It posits that pre-conditions are not necessary to establish trade integration. On the contrary, it is trade integration which will then leads to convergence. When countries integrate, there are basically leaders and followers. Thus, leaders like South African will be engaged in advanced research such as Science, Technology, Engineering and Mathematics (STEM) subjects which are core areas of the 4IR. It is through such technological advancements that these economies will gain from inventions, innovations and intellectual property rights thereby having a comparative advantage over smaller nations usually regarded as followers. At the same time, the view also argues that smaller nations will benefit because they can easily and cheaply 'imitate' these technologies and production processes thereby

accelerating their rate of growth and development leading to what is referred to as the ‘catch-up’ effect. Others also highlight that leading nations like South Africa will tend to gain from trade integration like AfCFTA because they will be able to easily and cheaply access regional markets for their efficiently and massively produced products, something which would not have been feasible had such integration arrangements not existed. Africa is largely characterised by high trade and non-trade barriers (NTBs). This has led to suppressed intra-trade levels of between 15%-18% (Pasara and Dunga, 2019; Mold and Mukwaya, 2017) compared to 60%-70% in the European and ASEAN communities. South African companies have found it challenging to expand into African markets despite them having sufficient capacity to do so. Thus, using the convergence (both ex-ante and ex-post) view, the AfCFTA does not only pose threats to the economy due to negative spill overs but also presents opportunities for expansion into regional markets.

Developments in new economic geography (Grossman and Helpman, 1991) can also be employed in the discussion. The model highlights that industries can be located in areas where there are abundant resources such as access to sea, natural endowments like minerals and favourable weather conditions and efficient transport infrastructure systems (Giroud and Mirza, 2006; Shaw et al. 1999). Complementary factors also include sound institutional frameworks (Hwang and Lee, 2015; Te Velde, 2011 and Law, 2006). South Africa is characterised by all these attributes which then explains, to some extent, why firms generally choose to concentrate their operations in the respective economy. The resultant effect is an uneven clustering of economic activities in South Africa compared to other African countries. This, as Pasara and Dunga (2019) highlighted, can lead to tensions among member countries as others would then feel the need to protect themselves against loss of position (Ujupan, 2005). Thus, economic and trade integration arrangements such as AfCFTA would lead to a ‘simultaneous process of agglomeration and decentralisation of sectorial activities’ which will in turn lead to an increase in both intra-sectoral and inter-sectoral trade.

Since there exists a bell-shaped link between transport costs and economic activities in a two-scenario economy where one is poorer and another is richer (Madariaga et al. 2003), empirical evidence suggests existence of divergent relationships across the NAFTA and Mercosur regions but positive relationship between density of economic activities and growth rate. Thus, using this analysis, it can be inferred that trade agreements such as the AfCFTA do not play significant role in the convergence process between those nations like South Africa who are aggressively pursuing 4IR policies and others like Zimbabwe and the rest of the member countries with a quiescent approach. In other words, although trade integration might present other benefits to South Africa, they are less likely to be in terms of its growth and development towards the 4IR. In fact, the new economic geography model postulates that disparities in wage rates and economic activities across economies can stimulate labour migration from poorer to richer economies thereby worsening the income inequalities and distribution (Pasara and Dunga, 2019b). Given the classical production function [$Q = f(L, K)$; output is a function of labour and capital], it is most likely that integration will lead to labour movement (from poorer to richer) as opposed to capital moving (from richer to poorer) economies. Prior to the AfCFTA, South Africa has already been experiencing an influx of labour migration from poorer nations thereby contributing to already existing challenges of structural unemployment.

On the other hand, prior free trade establishment such as SADC and the South African Customs Union (SACU) have benefited South Africa since most companies such as Unilever moved their headquarters from neighbouring countries into South Africa. The AfCFTA will likely compound to this effect leading to a greater concentration of industries and an even further acceleration of the growth and development of the 4IR agenda. This complements the empirical observation by Venables (1999) who observed that the production structure of Kenya moved was opposite of free market expectations. Kenya was able to expand its production base at the expense of poorer countries since they had to shift their manufacturing imports from the Rest of the World. This consequence was referred to as trade divergence by Viner (1950), a principle upon which our methodology will be anchored on. In the same vein, Tanzania and Uganda could not exploit the trade creation gains due to their limited product range. Thus, South Africa could gain because the 4IR will give it a comparative advantage over continental competitors in the AfCFTA.

Prior trade integration arrangements have led to mixed results, and it remains to be seen what the AfCFTA would bring. Investigating 29 Sub-Saharan countries, Ghura and Hadjimichael (1996) observed a 2% proclivity for income convergence. Using various models, Pasara and Dunga (2019a) and Mold and Mukwaya (2017) indicated that trade creation benefits outweighed trade diversion benefits. However, these gains are likely to lead to structural changes as some countries and economic sectors will gain at the expense of others. This study will add to this literature by focusing its analysis on how trade under the AfCFTA context will influence the industrial sector.

METHODOLOGY

The World Integrated Trade Solution-Software for Markets and Restrictions on Trade (WITS-SMART) simulation procedure developed by the World Bank was employed for this simulation. The rationale behind is because the AfCFTA is not yet being implemented, thus no existing trade data to employ alternative methodologies such as econometric models. Secondly, the WITS-SMART model is anchored on Jacob Viner's (1950) trade creation (and diversion) effects. The pros of the model are that it is able to employ trade data and perform simulations which produce results in terms of trade creation, diversion, revenue and welfare effects. Moreover, its data requirements are quite small compared to other models such as Computable General Equilibrium (CGE). The cons are that the model is static (as opposed to dynamic) and its focus on demand side economics. The paper rationally assumes infinite export elasticity implying changes in South African supply cannot influence world prices. Secondly, Armington's substitution assumption holds, that is, imperfect substitutes between domestic supply and import demand based in rules of origin for product differentiation (Armington, 1969). For instance, computing software from South Africa will be different from a similar software from any other African country since the intellectual property (IP) will be different.

The following equations will be estimated.

$$Cr_{iyz} = I_{ijk} * \eta * \frac{\Delta_{iyz}}{(1+t_{ijk}) * (1+\eta/\beta)} \dots\dots\dots (1)$$

- Cr_{ijk} = Trade created
- I_{ijk} = Imports
- t_{ijk} = Tariff
- η = elasticity of demand for imports

β = elasticity of supply for exports
 i = merchandise
 y = exporting nation
 z = importing nation

Equation (2) represents trade diversion which largely depends on the substitution elasticity:

$$Dv_{iyz} = \frac{M_{TFTA} * M_{RoW} \left[\left(\frac{1+t_t}{1+t_0} \right) - 1 \right] * \lambda}{M_{TFTA} + M_{RoW} + M_{RoW} \left[\left(\frac{1+t_t}{1+t_0} \right) - 1 \right] * \lambda} \dots\dots\dots (2)$$

Dv_{iyz} = Trade diverted

M_{TFTA} = Imported commodities from TFTA countries

M_{RoW} = Imported commodities from rest of the world

t_t = Tariff (where t_0 and t_t represent pre and post integration levels of tariffs)

λ = elasticity of substitution

The net trade effect (TE) is the summation of trade created and diverted:

$$TE = TC + TD \dots\dots\dots (3)$$

The net revenue effect (RE) in equation (4) indicates the revenue changes after a change in tariffs. It largely depends on price and volume of imports.

$$\Delta R_{izy} / R_{izy} = [\Delta t_{ijk} / (1 + t_{iyz})] * \eta * [(1 + \beta) / (\beta - \eta)] \dots\dots\dots (4)$$

ΔR_{izy} = The effects on revenue due to tariff changes

η = the elasticity of demand for the importing economy

t_{iyz} = Tariff

β = Elasticity of supply for the exporting economy

Equation 5 below estimates the welfare effects, which are the summation of the producer and consumers' surplus.

$$W_{iyz} = 0.5(\Delta t_{iyz} * \Delta M_{iyz}) \dots\dots\dots (5)$$

DATA DESCRIPTION

Data was sourced from the International Trade Center and the Harmonised Commodity Description and Coding System (HS) data format was used. The HS system allows traded goods to be classified on a common basis by participating countries for customs and related purposes. Globally, the HS is a six-digit code system which consists of around 5300 product descriptions, organised into 99 chapters and clustered into 21 sections. The six digits can be disintegrated into three parts: HS-2 identifies the chapter of the goods classification, HS-4 identifies groupings within that chapter, and the more specific HS-6. There are six (6) broad product classifications namely raw materials, intermediate goods, consumer goods, capital goods, agriculture, industrial and petroleum. However, this paper will focus on capital and industrial goods as proxies for the 4IR. The authors, however, acknowledges the applicability of 4IR across sectors like agriculture but they will not be considered for the purpose of this discussion as they are deemed indirect.

FINDINGS AND DISCUSSIONS SMART SIMULATION RESULTS

The results presented and discussed below are for only two product classifications as highlighted in the methodology section, that is, capital goods and industrial products for South Africa. The standard Harmonised System (HS) has a total of six product classifications as discussed earlier. Data was sourced from the International Trade Center (ITC) and the latest available data (2020) was used. The results were simulated under the underlying assumptions that supply elasticity is 99 which implies that changes within the South African productive capacity cannot influence world prices (practical assumption). Secondly, a substitution elasticity of 1.5 also implies that South Africa's technological developments as a result of the 4IR will be elastic which implies that it can be substituted with technologies from the Global North since they are most likely to be more likely to be invested in advanced research and technology than South Africa.

Table 1. Elasticities and Effects on Duty Rate

| Applied Duty Rate (Avg) | New Duty Rate (Avg) | Supply Elasticity | Substitution Elasticity | Old Weighted Rate | New Weighted Rate | Old Simple Duty Rate | New Simple Duty Rate |
|-------------------------|---------------------|-------------------|-------------------------|-------------------|-------------------|----------------------|----------------------|
| 6,834 | 6,387 | 99 | 1,5 | 1530 | 1573 | 654528 | 614491 |

The results indicate that applied duty rate will slightly decline from 6.83 to 6.39 once the AfCFTA is being implemented. Similarly, the simple duty rate will also decline from 654528 to 614491 reflecting a 6.5% change. However, the effect of the AfCFTA is that the weighted rate will increase from 1530 to 1575 (2.86%) for the two categorisations of industrial and capital goods.

Table 2: Effects on Exports and Imports

| Exports Before (USD 000) | Exports Before (Avg) | Exports After | Exports After (Avg) | Imports Before | Imports Before (Avg) | Tariff Revenue Before | Tariff Revenue New |
|--------------------------|----------------------|---------------|---------------------|----------------|----------------------|-----------------------|--------------------|
| 1688934 | 5071,873 | 1809842 | 5434,961 | 3426107 | 190339,3 | 12641 | 10139 |

The implementation of the AfCFTA under similar simulated conditions will lead to an increase in exports from 1 688 934 to 1 809 842 reflecting a change in exports of capital and industrial goods by 120 908 (approx. USD 121 million change). Since trade integration arrangements such as the AfCFTA implies removal of trade barriers like tariffs, it should be natural that tariff revenues will decline. Thus, in the case of the products under consideration, revenue declined from USD 12.7 million to USD 10.1 million. It is critical to note that these figures will become even significantly higher once all six product classifications are taken into account. Thus, the revenue loss is quite high. The implication of this revenue loss is that it is income which can be used by the government in the provision of public and merit goods such as street lighting, schools, roads and other services. Similar to most African countries, tariff revenue contributes a significant proportion of aggregate government revenue.

Table 3: Trade creation, Diversion, and Welfare Effects

| Trade Value (USD) | Trade Creation | Trade Diversion | Welfare Effects | Consumer Surplus |
|-------------------|----------------|-----------------|-----------------|------------------|
| 3426107 | No Effect | No Effect | No Effect | No Effect |

The total trade value for capital and industrial goods was noted to be around USD 3.4 billion. No trade creation and trade diversion effects were observed from this simulation. This is perhaps because no significant changes were observed for imports. The simulation is consistent with economic practicalities because South Africa is not a net importer of capital and industrial goods from other African countries. South Africa imports most, if not all, of its capital and industrial

goods either from developed countries like USA, Germany, United Kingdom or other emerging economies like the BRICS community. In fact, there are no African options to imports such goods due to capacity issues. The statistics could have been different had raw materials and agricultural goods been taken into account. Thus, as far as the 4IR revolution is concerned, South Africa is likely to benefit little from intra-African trade in terms of technological transfers. However, it will benefit from increased access to African markets as clearly reflected in the simulation results which showed an increase in exports.

CONCLUSION AND RECOMMENDATIONS

This paper discussed the influence of the AfCFTA towards the 4IR using WITS-SMART simulation analysis in South Africa by taking into account industrial and capital goods. Although majority of theoretical postulations are skewed towards the conclusion that trade integration is beneficial, this paper investigated this assertion based on Viner's model which indicates that conclusions are not obvious due to trade creation and diversion effects. Thus, taking into account the South Africa's National Development Plan (2030) which is hinged among other things on the 4IR, the study investigated how the AfCFTA could practically influence the 4IR policies. Results indicate that there will be an increase in net exports but no significant changes in imports leading to no effective trade creation and diversion effects for the two product classifications. Whilst the study suggests that South Africa can participate in the AfCFTA, the major highlight is that policy makers should not expect much influence with regards to the 4IR since majority of African countries do not have advanced technological (or STEM) integrated systems which would stimulate technological transfers among other things.

DETERMINANTS OF STUDENT SUCCESS AND BELONGING AMONG POSTGRADUATE ECONOMICS STUDENTS

Z. Robinson

University of South Africa, Pretoria, South Africa

M.D. Uys

University of South Africa, Pretoria, South Africa

ABSTRACT

The purpose of the Economics honours research report module at the University of South Africa (Unisa) is to guide students in putting together a research paper that demonstrates their ability to conduct guided research in the local context. This paper analyses the determinants of factors that best explain student success and belonging in this module. This study is divided into five sections. The first section describes the background and introduction. The second section presents a literature review. The third section describes the research methodology. The fourth section entails a summary of the results and the last section concludes the study. The study reported in this paper employs a quantitative methodology with an econometric analysis of the dependent variable namely the final marks for the research report and the independent variables that explain it. The results show significance in terms of the assignments and existing knowledge marks in terms of their B Com average mark. However, demographic factors are insignificant, showing that other factors such as the supervision and the holistic experience become more important for postgraduate students. This is also the first evidence of self-directed learning during the COVID-19 pandemic.

1 BACKGROUND AND INTRODUCTION

The Bachelor's Honours Degree is a postgraduate specialisation qualification on South Africa's National Qualification Framework (NQF). It is awarded at NQF level 8. In some countries, this qualification is offered as an undergraduate degree to prepare students for postgraduate study. However, in South African universities, this degree is meant to prepare students for research-based postgraduate study. Unisa is one of the universities offering the Honours degree at a postgraduate level. Examples of honours degrees at this university include Bachelor of Commerce Honours, Bachelor of Social Science Honours, Bachelor of Arts Honours, and Bachelor of Science Honours.

Unisa celebrates its 149th birthday in 2022. It is regarded as the first of its kind in the world, namely, a single-mode distance education institution (Peters, 2010 p. 57). As a mega university, it is also Africa's leading open distance learning (ODL) university. Unisa's vision and mission statements, as well as the motto "Define tomorrow", relate to its African but also futuristic character (Unisa, 2016). The open nature of the university means that it also caters to the underprivileged. Therefore, the academic staff at Unisa need to deal with a range of unemployed, young students that are digital learners chatting online in groups (Letseka & Pitsoe, 2013). Van Niekerk, Heydenrych and Higgs (2003) warn against merely duplicating the print-based effort online with no actual learning taking place. Guri-Rosenblit (2009) says that universities might have to be redesigned, and may have to adjust their strategy to cope with the online and virtual context.

The vision and mission statements of Unisa relate to the African character of the university, with open learning catering for quality life-long learning. A further key point in the mission statement refers to addressing the needs of a diverse learner profile by offering relevant learner support, facilitated by appropriate information and communications technology (ICT) (Unisa, 2010). E-learning or technology-enhanced learning can assist South Africa and the African continent's young population to stay relevant, vibrant and progressive within the fast-paced modern society. Mobile learning via smartphones tends to augment e-learning, rather than replace it (Macdonald & Chiu, 2011). The African continent has become more connected, with interconnectivity at the doorstep of most learners (Unisa, 2010).

In the workplace, more emphasis is on skills and abilities than on academic knowledge (Royal Bank of Canada, 2018). Therefore, universities need to produce research and graduates that are relevant to industry or employment to optimise their contribution to the workplace. To remain at the forefront of tertiary economics tuition in South Africa, the Department of Economics needs to be cognisant of the changing world, and the resultant demands and expectations of research and graduates by industry. The Department of Economics at Unisa has consequently expressed a need to review the degree curriculum by seeking input and perceptions from key stakeholders such as business, alumni and academic staff members. Such a review intends to prepare students for the demands of the current and future workplace more effectively and proactively. As such, graduateness usually covers the following key aspects (Coetzee et al., 2012):

- A suite of attributes that graduates acquire during their university study;
- The relationship between graduateness and employability, including employer needs and expectations; and
- Student attitudes and orientation towards the labour market.

Therefore, this paper is the first attempt of investigating student success and ultimately belonging within an online environment. The evaluation of the Economics honours degree offering through student progress and value accretive initiative, which together with the College of Economics and Management Sciences (CEMS) (Unisa) transformation agenda, as initiated in 2017, will foster and create a world-class, though still uniquely African offering.

The objective of the study reported on this paper is to find the factors that best explain the student performance in the Honours Economics Research report. Challenges faced and issues arising may include pedagogic interventions but also assisting with a more efficient, effective and economic open distance e-learning (ODeL) environment.

2 LITERATURE REVIEW

Student success/throughput “is one of the most widely studied issues in higher education over the past twenty-five years” (Tinto 2002: 2). Although this research resulted in “an ever more sophisticated understanding of the complex web of events that shape student leaving and persistence, most institutions have not yet been able to translate what we know about student retention into forms of action that have led to substantial gains in student persistence and graduation” (Tinto 2006: 1, 5).

The most compatible model with our analysis in this paper is probably Bean's causal path model (1980); (1982). The background variables are performance, socioeconomic status, state residence, distance from home, and hometown size. The determinants are institutional quality, integration,

university grade point average, goal commitment, communication, requirements (rules), distributive justice, advisor, staff/faculty relationship, housing, and campus organisations. The intervening variables are satisfaction and institutional commitment.

The focus will fall on more recent studies in the South African education environment (curriculum research also) and not just within an ODeL environment. Keeve, Naude and Esterhuyse (2011:121) found that for three-year–curriculum students, academic factors such as Grade 12 performance and language proficiency provide a significant explanation. This does not apply to four-year-curriculum students where psychosocial factors such as parents' education level play a role. Following a study by Davis and Venter (2011), the contributing factors of postgraduate honours business management, student success pertains to formative assessment, student enjoyment of the course, lecturer involvement and attendance of course workshops. In terms of international postgraduate students, key factors of academic success relate to good supervision mechanisms, student adjustment programmes offered for students to adjust within the country of learning, workshops and financial services, library services and individual characteristics of international students (Kaur & Singh, 2018). Rashied and Inglesi-Lotz (2017) found that the student-to-supervisor ratio has no significant impact on the research proficiency of an Economics Honours student. This shows that various other factors influence the research proficiency of these students. Financial difficulties, personal challenges and fewer opportunities for students to get study leave from employers can also impact throughput (Botha, 2018). Various articles refer to the importance of supervisory skills and relationships in academic success (Roongtawanreongsri & Awour 2018; Unsworth *et al.* 2010).

3 RESEARCH DESIGN AND METHODOLOGY

The honours research report module aims to guide students in putting together a research paper that demonstrates their ability to conduct guided research in the local context. This is a 36-credit module and is presented online. They can only choose a research topic in one of the two elective modules for which they were registered or are currently registered. Their choice of research method can be either qualitative (or descriptive-analytical) or quantitative (or empirical-econometric). Each student will be allocated a supervisor. The module format is fully online. The module aims to equip students with the competencies required to plan, execute and write an acceptable academic research paper in Economics. Students will be able to reason, debate in a written format a specific economic topic, recognise existing international and national research on the topic, and integrate appropriate research methodologies in Economics. The data for the empirical analysis drew on the year 2021. This sample comprised approximately 220 students, with 152 students retained for analysis. More importantly, ethical clearance was granted for the study.

3.1 Profile of students

The group comprised mainly females with a mean age of approximately 32, and where students mostly did not study in their home language (Table 1). The home language is included in the analysis as a reliable indicator of student success. Students must submit four assignments during the year, with the last assignment also serving as examination. For this study, the handing in and passing of the four assignments were taken as showing effort and commitment on the part of the student.

Table 1: Descriptive statistics

| | FINAL_MARK | AGE | FT_STUDENT | HL_ENG | M_F | B_COM_AVE | ASS1 | ASS2 | ASS3 | ASS4 |

3.2 Empirical methodology and model specifics

To assist the student, we needed to understand the determining factors in terms of student performance. The model was designed according to previous literature as discussed earlier but additional variables have also been chosen to support the discussion behind the success rate and belonging of Economics honours students at the fourth-year level, namely:

$$OUTPUT \text{ Final_mark_Hon_Ecn} = f(\text{Age}, \text{Dum_fulltime}, \text{Dum_HL}, \text{Dum_male}, \text{Final_mark_B Com_Average}, \text{Ass_1}, \text{Ass_2}, \text{Ass_3}, \text{Ass_4}).$$

The dependent variable effectively reaches the final mark while using a dummy variable to indicate pass or failure.

The coefficients, or explanatory variables, consisting of the following: Age, dummy time variable ('Dum_fulltime', with a value of 1 for full-time study, else 0), dummy language variable ('Dum_HL', with a value of 1 for study in the home language, else 0), dummy gender variable ('Dum_male', with a value of 1 if for male, else 0 if female); final mark reached in B Com_Average, Assignment marks).

Table 2: Description of variables for Economics Honours Research report

| Dependent variables | |
|--------------------------|---|
| Finalmark_Hon_Ecn | Final mark scored by the student in Economics Honours Research report |
| Dum_Final | Taking a value of 1 if passed and 0 if failed |
| Explanatory variables | |
| Age | Age of the student |
| Assignment_1 | Mark of assignment 1 |
| Assignment_2 | Mark of assignment 2 |
| Assignment_3 | Mark of assignment 3 |
| Assignment_4 | Mark of assignment 4 |
| Dum_HL | Taking a value of 1 if studying in the home language and 0 if not |
| Dum_Male | Taking a value of 1 for male students and 0 for females |
| Dum_full | Taking a value of 1 for full-time students and 0 for part-time |
| Final_mark_B Com_Average | Final mark B Com Average |

The assignment weight contribution is covered in the following Table 3:

Table 3: Year mark contribution

| Assignment | Year mark contribution | Type |
|------------|--|---|
| 01 | Contributes 10% towards year mark (3% towards final mark) | MCQs and Research topic and method and declaration |
| 02 | Contributes 40% towards year mark (12% towards the final mark) | Research proposal |
| 03 | Contributes 50% towards year mark (15% towards the final mark) | Report including: a) detailed literature review and methodology b) estimation results (quantitative) and improved proposal (qualitative); c) Conclusions, recommendations and abstract |
| 04 | Contributes 70% towards year mark | Final research paper |

4 RESULTS AND DISCUSSION

The results suggest that the final marks of first-, second-, third and fourth assignment marks significantly impact the final mark (Table 4). This was obvious and expected looking at these assignments' weight contribution. The better the student performs in the assignments, the better the student's final mark. However, home language does not turn up as a contributor, because these students can be regarded as more senior and mature in their studies. Indeed, many of the students can be considered as studying part-time, and they may be active in an environment where English is the main language of communication.

Table 4: Ordinary least squares with final mark Hon_Ecn as dependent

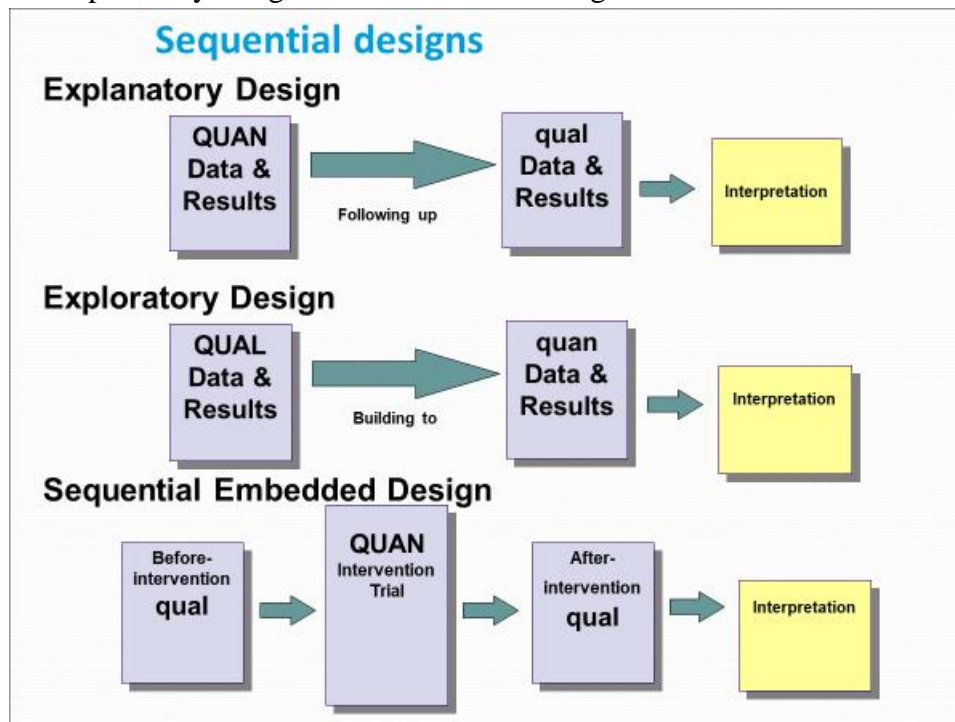

| Variable | Coefficient (2021) | Prob. |
|----------------------|--------------------|--------|
| C | -2.344034 | 0.0273 |
| FINMRK_B_Com_Average | 0.043496 | 0.0041 |
| DUM_FULL | 0.552986 | 0.2196 |
| DUM_HL | -0.586810 | 0.1959 |
| DUM_MALE | 0.173407 | 0.6025 |
| AGE | -0.008494 | 0.7335 |
| ASS 1 | -0.014382 | 0.0393 |
| ASS 2 | 0.033473 | 0.0019 |
| ASS 3 | 0.029938 | 0.0096 |
| ASS 4 | 0.960947 | 0.0000 |
| R-squared | 0.990123 | |
| Observations | 137 | |

Within age and the status of the student, full-time or part-time, the results tend to show insignificant outcomes. Existing knowledge from the B Com average shows significant results and confirm that pre-existing knowledge matter (Athey et al., 2007). The literature review in this paper also confirms the results. Our binary logit results turned out to be insignificant.

This study adopted a quantitative approach from secondary data. We hope to make it a mixed-methods study going forward. In this regard, we are hoping to collect primary data from the 220 registered Economics honours Unisa students of 2021 through a survey designed on Qualtrics.

This will also expand the research questions from demographic factors and subject knowledge including assignments to supervisor influence and other factors in terms of experience or belonging that play a role (see anonymous link at https://unisa.qualtrics.com/jfe/form/SV_9GFV9IKZuIk881U). Furthermore, this will also expand the study to include the drop out and retention factors. We are hoping to get more responses and feedback from this survey and

do more qualitative research in terms of this in future. This will make it a mixed-methods, sequential and explanatory design as seen in the next diagram.

5 CONCLUSIONS

The Economics honours research report module at Unisa aims to guide students in putting together a research paper that demonstrates their ability to conduct guided research in the local context. This paper analysed the determinants of factors that best explain student success and belonging in this module. This paper is divided into five sections. The first section describes the background and introduction. The second section presents a literature review. The third section describes the research methodology. The fourth section entails a summary of the results, and the last section concludes the study. The study employed a quantitative methodology with an econometric analysis of the dependent variable namely the final marks for the research report and the independent variables that explained it. The results show significance in terms of the assignments and existing knowledge marks in terms of their B Com average mark. However, demographic factors showed up insignificant, showing that other factors such as the supervision and the holistic experience (including belonging) become more important for postgraduate students. We have sent out a satisfaction survey to honours students to gain more insight and will in future extend the current study to mixed methods analysis. We hope to have more data analysis and results available during the conference in October 2022.

SSIRC 2022-015

VALIDATION OF THE DAILY SPIRITUAL EXPERIENCE SCALE IN A GROUP OF BLACK SOUTH AFRICAN STUDENTS

I.M. Shube

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

This study aimed to validate the English version of the Daily Spiritual Experience Scale (DSES) in a group of $N = 324$ black South African students. Validation studies are important in Global South contexts, because they facilitate the broadening in understanding of psychological and psychometric phenomena, in general, and more specifically, validating psychometric instruments allows for a better understanding of psychosocial and existential phenomena in specific groups of people. Validation of the DSES was done by investigating its internal consistency, reliability, factorial validity, and convergent and divergent validity. The DSES had reliability of 0.85, a unidimensional factor structure, and showed convergent validity by significantly correlating with the Mental Health Continuum (MHC), and divergent validity by significantly correlating with the Patient Health Questionnaire (PHQ). The unidimensional, 16-item DSES is valid for use in a South African black student context as a domain general measure of spiritual experience.

Keywords: Compassion; daily spiritual experience; gratitude; love; mental health; spirituality; spiritual well-being; transcendence; well-being.

1. INTRODUCTION

Spirituality has gained traction in the field of positive psychology and well-being science, that aims to focus on supporting and encouraging positive internal resources by promoting subjective well-being and complete mental health (Seligman & Csikszentmihalyi, 2014). Spiritual well-being as a construct is continuously being theorised and clarified; initially, this occurred within the realm of religiosity but later, in the realm of spirituality and spiritual well-being (Pargament, 2007), and as an important component of complete mental health. The aim of this study was to validate the Daily Spiritual Experience Scale (DSES) (Underwood & Teresi, 2002) in a South African student group.

Spirituality, religiosity and spiritual well-being

Spirituality as an overarching site of inquiry has generally fallen within the disciplines of philosophy and theology, often grouped with religiosity, and placed within subjective well-being studies. However, spiritual well-being can rather be understood to fall within eudaimonic well-being that emphasises positive psychological functioning and meaning in life (Steger, Frazier, Oishi, & Kaler, 2006), gratitude, transcendence, and compassionate love (Underwood & Teresi, 2002). What follows is a brief description and definition of the constructs that are currently understood to form part of what is comprehensively known as spiritual well-being: spirituality, religiosity, spiritual well-being, and presence of mental health.

Spirituality

Spirituality and the experience of spiritual phenomena are present in the lives of most people (Emmons, 2000; Jantos & Kiat, 2007; Moberg, 1971; Underwood, 2006, 2011). Some facets of spirituality are often latently prevalent within interventions that promote well-being (Good & Willoughby, 2005; Piedmont, 1999; Underwood, 2011). Scientific studies that focus on spirituality have increased, and these studies are evidence that differences exist in conceptualising and operationalising the construct of spirituality. Despite these differences, the consensus is clear: spirituality plays an important positive role in enhancing individuals' well-being (Kalkstein & Tower, 2009; Moberg, 1971; Piedmont, 1999; Underwood, 2011; Underwood & Teresi, 2002). Emmons (2000) conceptualised spirituality as an intelligence with features such as transcendence and heightened states of consciousness and individual virtue sanctifying the mundane, as well as a source of problem-solving abilities in individuals. Wheeler, Ampadu, and Wangari (2002) further conceptualised spirituality as a social phenomenon, stating that spirituality is socially derived, inherently human, and functions as an internal psychosocial resource (Wheeler et al., 2002). Kalkstein and Tower (2009), therefore, emphasised that any definition of spirituality would have to be comprehensive and inclusive of context, practice, ritual, culture, as well as various other factors.

Religiosity and spiritual well-being

Literature on the conceptual distinction between spirituality and religiosity overlaps to a great extent, and research has found that spirituality and religiosity are statistically related (Dein, 2005; Hill et al., 2000). Hill et al. (2000) argued that a distinction between religiosity and spirituality should be approached with a deep understanding of the contextual overlap that exists in the nature and experience of spirituality and religiosity, while Hill and Pargament (2003), additionally, cautioned against separating the two constructs because doing so could yield superficial understanding of these concepts in the normal day-to-day lives of individuals. More specifically, Piedmont (2004) stated that spirituality is an individual attribute, and that religiosity, an institutional attribute. Good and Willoughby (2005) referred to spirituality as an individual's personal beliefs or intrinsic commitment to such beliefs; spirituality seems to be more inclusive in understanding the phenomenon of searching for the sacred, whereas religion refers to a search that is based specifically in traditional religious contexts and religious institutions. Spirituality and religiosity both comprise of a need to relate to a higher transcendent being or deity and, oftentimes, require an ability to transcend the self (Paloutzian & Park, 2005). Spirituality is concerned with the transcendent and addresses issues related to worldview and the meaning of life – it is possible to be spiritual while not being religious (Good & Willoughby, 2005; Underwood & Teresi, 2002). Sanchez, Arocena, and Ceballos (2010) found that those who were identified as atheist or agnostic, reported a higher frequency of spiritual experience. However, it is important to keep in mind that for most people, spirituality is often experienced within religious contexts (Hill & Pargament, 2003).

Spiritual well-being

Spiritual well-being is the perceived life-long presence (Moberg, 1984) and experience of transcendence, gratitude, and compassionate love in individuals' lives (Underwood, 2011). The prominent role of spiritual well-being, transcendence, and daily spiritual experience in general

health and wellness has been alluded to by previous research on spirituality (Moberg, 1971, 1984; Emmons, 2000; Jantos & Kiat, 2007; Underwood, 2011). Spiritual well-being is a predictor of positive outcomes, such as better performance of health behaviours and lowered alcohol intake (Kalkstein & Tower, 2009; Underwood, 2011), positive psychological adjustment (Van Dyke, Glenwick, Cecero, & Kim, 2009), decreased psychopathology (Kalkstein & Tower, 2009), decreased familial conflict (Kwon, 2008), and improved relational well-being (Kalkstein & Tower, 2009). Spiritual well-being is central in encouraging adaptive behaviour (Kalkstein & Tower, 2009; Underwood, 2011).

2. LITERATURE REVIEW

Traditionally, spiritual well-being has been measured along with religiosity or religious affiliation and participation. However, it is important to focus on spiritual well-being because it is increasingly found to be important for overall well-being. Some of the scales that measure spirituality are: The Spiritual Experience Index (SEI), that measures faith and the spiritual journey (Genia, 1991, 1997); the Spiritual Well-being Scale (SWBS), that focuses on perceived states of religiosity and existential well-being (Paloutzian & Ellison, 1982); and the Spiritual Health and Life-Orientation Measure (SHALOM) (Fisher, 2010, 2016), that aims to measure spiritual health or well-being by assessing quality of intra and interpersonal relationships as well as individuals' relationships with their immediate and extended socio-spiritual environments, including a relationship with a higher supernatural being (Fisher, 2010, 2016).

There are several psychometric instruments that specifically focus on examining the relationships between spirituality and psychological constructs; for example, between a daily spiritual experience and temporal changes (George & Park, 2013; Tong, 2017), alcohol abuse (Churakova, Burlaka, & Parker, 2017), meaning in life (George & Park, 2017; Meng & Dillon, 2014; Wnuk & Marcinkowski, 2014), as well as positive coping strategies such as managing burnout, life satisfaction, well-being, and prosocial behaviours (Underwood & Teresi, 2002; Underwood, 2011). The DSES has been consistently found to have a positive relationship with psychological adjustment (Underwood, 2006, 2011), and a negative relationship with maladaptive social behaviours (Lee, Veta, Johnson, & Pagano, 2014).

Daily Spiritual Experience (DSE)

The Daily Spiritual Experience (DSE) was conceptualised as part of understanding the non-religious spiritual experiences of individuals in healthcare settings, and in the individuals' general day-to-day lives (Underwood, 2006). The DSE considers individuals' perceptions of the transcendent in their day-to-day lives, with the focus being on the spiritual and experiencing spirituality, rather than religion or theistic affiliation and ritual (Underwood & Teresi, 2002). There are three important components of the DSE construct, namely: gratitude, transcendence, and compassionate love.

Gratitude

Gratitude is a state of appreciation for having received help which is perceived to be of great value (Wood, Froh, & Geraghty, 2010) and is accompanied by feelings of appreciation when experiencing altruistic deeds, helpfulness (Froh et.al, 2009), and can be directed inwards, towards objects, the metaphysical, and the spiritual. A trait level positive life orientation (Wood, Joseph,

Llyod, & Atkins, 2009; Froh et.al, 2009) and increased well-being, are features of gratitude (Winfield, 2013).

Transcendence

Transcendence is a core component of spirituality (Emmons, 2000) and spiritual well-being. Transcendence is inherent in individuals and is the sense of experiencing divinity or the divine. Transcendence can act as a source of motivation or innate need that influences behaviour (Piedmont, 1999, 2004). Kwon (2008), however, warned that seeking to continuously experience transcendence may lead to detachment from reality.

Compassionate love

Compassionate love is an altruistic love that extends to humanity, in general, and is defined as “a type of love that can be experienced for a variety of others, including all of humankind” (Sprecher & Fehr, 2005, p. 630).

In the seminal study, Underwood and Teresi (2002) found that the DSES had good construct validity when correlated with health and quality of life variables; a finding that was supported by research conducted by Kalkstein and Tower (2009). The DSES has been translated into various languages and validated in several populations globally (Underwood, 2011).

Complete mental health

Complete mental health is central to health, well-being, and policy. In its definition of overall health, the World Health Organization (WHO) includes complete mental health and social well-being as core indicators of general health and well-being. An individual is considered to have complete mental health when they are physically, mentally, and socially well; there should be a presence of health and not merely an absence of illness (WHO, 2007). Healthy individuals have agency and internal resources to manage and cope with daily stressors, and can contribute meaningfully to their communities (WHO, 2007). Galderisi, Heinz, Kastrup, Beezhold, and Sartorius (2017) state that mental health is a dynamic state of internal equilibrium which enables individuals to use their abilities in harmony with universal values of society; they explain that basic cognitive and social skills – the ability to recognise, express and regulate emotions, ability to empathise, flexibility and an ability to cope with challenges, to function in social roles and harmonious relationship between body and mind – represent important components of mental health, which contribute to the state of internal equilibrium (2017, p. 408).

The complete mental health construct (Keyes, 2014) comprehensively includes emotional, psychological, and social well-being characterised by positive feelings (e.g., happiness; satisfaction), positive attitudes towards one’s own responsibilities and towards others, and positive social functioning (e.g., social integration, actualisation, and coherence). According to Keyes (2002), complete mental health manifests on a continuum of functioning, ranging from flourishing or feeling and functioning well, to languishing or feeling and functioning un-well. The complete mental health theory was operationalised by the Mental Health Continuum Scale, that is currently one of the most frequently used measurements of constructs such as flourishing, optimal mental health, psychological well-being and more (Khumalo, Wissing, & Schutte, 2014).

Measurement in different cultural contexts

Valid and reliable measuring instruments cannot be assumed to be appropriate in all contexts or across populations. This is an important consideration when using psychometric instruments because scale items may operate differently across cultures (De Kock, Kanjee, & Roodt, 2013), which could result in item bias. Measuring instruments should be validated for the populations for which they will be used (Cromhout, 2015), so that there is a reduction of implicit bias and language barriers. Such validation ensures fairness and cultural ‘fit’ of measurements (De Kock et al., 2013; Foxcroft & Roodt, 2009).

The aim of this study was, therefore, to validate the DSES in a black South African student group. The objectives were to investigate (1) the internal consistency reliability of the DSES, (2) the factorial validity of the DSES, and (3) the convergent and divergent validity of the DSES within a black South African student population.

3. METHODOLOGY

This study aimed to validate the English version of the DSES in a black South African student sample, by investigating the validity and reliability of the scale. The objectives set were to investigate: the internal consistency reliability of the DSES; the factorial validity of the DSES; and lastly, the convergent and divergent validity of the DSES.

3.1 Research design and sampling method

This study followed a quantitative approach (Creswell, 2013; Frels & Onwuegbuzie, 2013) with a cross-sectional design. Data was collected from black students at a South African university, by providing participants with a link to a survey that they completed in their own time, but within a set submission deadline. The sample consisted of $N = 324$ participants between ages 18 and 44 (male = 140; female = 184; mean = 1.57; $SD=0.50$), enrolled in different courses at different levels of study. All survey items were in English as it is the language of teaching and learning at this university.

3.2 Data collection

Data collection was carried out through a biographical questionnaire about gender, population group, and religious affiliations, as well as the following validated questionnaires: The Daily Spiritual Experience Scale (DSES) (Underwood & Teresi, 2002); the Mental Health Continuum – Short Form (MHC-SF) (Keyes, 2002, 2006; Keyes et al., 2008); and the Patient health questionnaire (PHQ-9) (Kroenke, Spitzer, & Williams, 2001).

Daily Spiritual Experience Scale (DSES)

Underwood and Teresi’s (2002) DSES is a 16-item scale measuring daily spiritual experience (DSE). The DSES taps into dimensions of spirituality such as mercy, gratitude, awe, and a sense of connection with the transcendent, including feeling compassionate love. Participants are asked to indicate how often they have experienced an item; leeway is given to participants who do not identify with a deity, and they are encouraged to substitute another word that calls to mind the divine or holy for them (Underwood & Teresi, 2002). This unidimensional scale has been validated in several populations globally (Underwood, 2011). In a Chinese group, the DSES was found to

be valid and reliable (Cronbach alpha was 0.97) (Ng et al., 2009), and in a Brazilian sample, the scale was found to have temporal stability (Kimura et al., 2012). In a review of the use of the scale, Underwood (2011) found evidence of good psychometric properties and internal consistency with high validity and reliability scores (Cronbach alpha above 0.90). The DSES has been found to have good construct validity when correlated with measures of positive well-being, as was reported by Underwood and Teresi (2002), as well as in later research by Kalkstein and Tower (2009). The DSES has not been used for research in the South African context; this study was the first in validating the scale (Shube, 2020).

Mental Health Continuum– Short Form (MHC-SF)

The MHC-SF, developed by Keyes (1998, 2002, 2006), is a 14-item questionnaire measuring positive mental health. It has a three-dimensional factor structure which consists of emotional well-being (EWB; 3 items), psychological well-being (PWB; 6 items), and social well-being (SWB; 5 items). This three-dimensional factor structure has been confirmed in multiple countries across the world, including the United States of America (Keyes, 2002), the Netherlands (Lamers, Westerhof, Bohlmeijer, ten Klooster, & Keyes, 2011), and South Africa (Keyes et al., 2008). The MHC-SF has been found to be reliable (0.57 and 0.71) with adequate construct validity (Keyes, 2002, 2006). Lamers et al. (2011) found that among a Dutch sample, the MHC-SF had high test-retest reliability over time. Specifically, in relation to the context of this study, the MHC-SF has been validated and found reliable (reliability score of 0.74) and valid in a South African youth population (Keyes et al., 2008). The three subscales of the MHC-SF have shown positive correlations with other measures of positive mental health, such as improved health, and overall improved adaptive behaviour (Liang, Tracy, Kenny, Brogan, & Gatha, 2010).

Patient Health Questionnaire (PHQ-9)

The Patient Health Questionnaire (PHQ-9, developed by Kroenke et al. (2001), is a 9-item scale used to assess symptoms of depression and other mental illnesses encountered in healthcare settings. The scale is unidimensional and measures symptoms of depression according to nine criteria of the *Diagnostic and Statistical Manual IV (DSM-IV)*. Along with these nine items, the PHQ-9 has an additional item that evaluates the influence of depression experienced in everyday life. The PHQ-9 had an internal consistency reliability of 0.89 and 0.86 in the initial validation studies (Kroenke et al., 2001), and has been validated for use in different contexts, including predominantly African populations (Adewuya, Ola, & Afolabi, 2006; Richardson, McCauley, & Grossman, 2010). Adewuya et al. (2006) validated the PHQ-9 for use among Nigerian students, where the test-retest reliability indices of the PHQ-9 have consistently been found to be above 0.65 (Adewuya et al., 2006; Kroenke et al., 2001; Richardson et al., 2010). The PHQ-9 has also been used in South African research by Botha (2011), Cromhout (2015) and Smith (2018), who all reported high reliability for the scale.

3.3 Data analysis

Data was analysed in four stages using the Mplus Version 8.2 statistical analysis software program (Muthén & Muthén, 1998-2017). Descriptive statistics were calculated, and confirmatory factor analysis was done to establish factorial validity and internal consistency reliability. Convergent validity was established by correlation patterns between the scores of the DSES and the subscales

of the MHC-SF (EWB, PWB, SWB). Divergent validity was established by correlation with a depression measure (PHQ-9).

4. RESULTS

4.1 Descriptive statistics, reliabilities, and correlations

In Table 1a, descriptive statistics, reliabilities, and correlations for *convergent validity* of the DSES are given, while in Table 1b, descriptive statistics, reliabilities, and correlations for *divergent validity* of the DSES are provided. SPSS 25 (IBM Corporation, 2017) was used to calculate means and standard deviations, while MPlus 8.2 (Muthén & Muthén, 1998-2017) was utilised for all other analyses. The mean scores of scales and sub-scales ranged between 2.53 for MHC-SWB, and 3.85 for MHC-PWB, with standard deviations of 0.61 for the PHQ ranging to 1.08 for MHC-SWB (see Tables 1a and 1b). These indices compared well with those reported in literature for the DSES, the MHC-SF, and the PHQ-9 (Keyes, 2002, 2006; Keyes et al., 2008; Kroenke et al., 2001; Underwood, 2011).

Table 1a: Descriptive statistics, reliabilities, and correlations for convergent validity

| Variable | M | SD | ρ | Corr (DSES) |
|-----------------------------------|------|------|--------|-------------|
| DSES | 3.63 | 0.62 | 0.85 | 1.00 |
| MHC-SF - Complete | 3.31 | 0.77 | 0.84 | 0.32†** |
| MHC-SF - Emotional well-being | 3.52 | 1.04 | 0.74 | 0.23** |
| MHC-SF - Psychological well-being | 3.85 | 0.82 | 0.76 | 0.30** |
| MHC-SF - Social well-being | 2.53 | 1.08 | 0.74 | 0.16* |

* $p < 0.05$ ** $p < 0.01$ † $r > 0.30$ = medium practical affect

Table 1b: Descriptive statistics, reliabilities, and correlations for divergent validity

| Variable | M | SD | ρ | Corr (DSES) |
|----------|------|------|--------|-------------|
| DSES | 3.63 | 0.62 | 0.85 | 1.00 |
| PHQ | 2.00 | 0.61 | 0.81 | -0.02 |

Internal consistency reliability of the DSES, calculated with MPlus 8.2, is a composite reliability value with the same preferred cut-off values as Cronbach's alpha (0.70) (Muthén & Muthén, 1998-2017). Therefore, as shown in Tables 1a and 1b, the reported reliability indices (ρ) for the DSES, the MHC-scales and the PHQ, that were between 0.74 (MHC-EWB) and 0.85 (DSES), could be considered as acceptable (Raykov, 2009).

Internal consistency reliability of the DSES, calculated with MPlus 8.2, is a composite reliability value with the same preferred cut-off values as Cronbach's alpha (0.70) (Muthén & Muthén, 1998-2017). Therefore, as shown in Tables 1a and 1b, the reported reliability indices (ρ) for the DSES, the MHC-scales and the PHQ, that were between 0.74 (MHC-EWB) and 0.85 (DSES), could be considered as acceptable (Raykov, 2009).

4.2 Factor structure of the DSES

The factor structure of the DSES, as depicted in Table 2, was verified by means of MPlus 8.2 (Muthén & Muthén, 1998-2017), using confirmatory factor analysis (CFA). The robust maximum likelihood (MLR) estimator was used due to skewness and kurtosis present in the data. To determine fit, the following indices were reported: χ^2 with its associated degrees of freedom; the MLR-adjusted χ^2 ; the comparative fit index (CFI) and the Tucker-Lewis index (TLI), both with values >0.90 , indicating acceptable fit; the root mean square error of approximation (RMSEA),

for which 0.05 – 0.08 is seen as a range of excellent to acceptable fit; and the standard root mean square residual (SRMR), with less than 0.08 indicating a good fit (Wang & Wang, 2012).

Table 2: Fit statistics of confirmatory factor analysis of DSES

| Model | χ^2 | df | MLR-adjusted χ^2 | CFI | TLI | RMSEA | SRMR |
|-------|----------|-----|-----------------------|------|------|-------|------|
| DSES | 204.01 | 101 | 251.92 | 0.92 | 0.90 | 0.06 | 0.05 |

χ^2 = Chi-square; df = degrees of freedom; MLR = Maximum Likelihood (Robust) estimator; TLI = Tucker-Lewis Index; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation; SRMR = Standardized Root Mean Square Residual.

Table 2 displays these fit values that indicate a good statistical fit and confirms the unidimensional factor structure of the DSES as proposed by Underwood and Teresi (2002).

4.3 Convergent and divergent validity of the DSES

Convergent validity

A measurement model containing only the DSES items and the MHC-SF items (EWB, SWB and PWB combined into an MHC second order latent variable) was specified to check for model fit. It was found that items 13 and 14 of the DSES, and item 4 of the MHC-SF had low factor loadings (<0.35), and the error variances of DSES 13 and MHC 4 showed a high modification index. As a result, these three items were removed from further analyses. Error variances were, however, allowed to correlate between DSES 1 and 2, DSES 4 and 5, DSES 10 and 11, and MHC 11 and 14. The developed measurement model (see Table 3a) showed good fit and a significant correlation of 0.32** (see Table 1a), between the DSES-factor and the MHC-factor, proving convergent validity of the DSES.

The process was repeated, but with EWB, SWB, and PWB specified without an MHC second order latent variable. This was done to determine possible convergent validity between the DSES and the three factors (EWB, PWB, SWB) underlying a total well-being score. The same items were removed, and the same error variances allowed to correlate. The model showed good statistical fit. Significant correlations (see Table 1a) were found between the DSES-factor and the three separate factors of the MHC, further confirming convergent validity, even though SWB showed a correlation at a lower level of significance ($p < 0.05$) than EWB and PWB ($p < 0.01$). Table 3a shows the fit statistics of the measurement models for convergent validity, where Model 1 represents the measurement model including the second-order latent variable MHC, and Model 2, the measurement model with the three latent variables (EWB, PWB, SWB) specified separately.

Table 3a: Fit statistics of measurement models for convergent validity

| Model | χ^2 | df | MLR-adjusted χ^2 | CFI | TLI | RMSEA | SRMR | Model | χ^2 |
|---------|----------|-----|-----------------------|----------|----------|-------|------|-------|----------|
| Model 1 | 527,22 | 316 | 605,67 | 25142,14 | 25478,35 | 0,91 | 0,90 | 0,05 | 0,06 |
| Model 2 | 524,26 | 314 | 602,69 | 25143,18 | 25486,94 | 0,91 | 0,90 | 0,05 | 0,06 |

Table 3b: Fit statistics of measurement model for divergent validity

| Model | χ^2 | df | MLR-adjusted χ^2 | CFI | TLI | RMSEA | SRMR | Model | χ^2 |
|---------|----------|-----|-----------------------|----------|----------|-------|------|-------|----------|
| Model 3 | 390,62 | 224 | 439,10 | 19266,21 | 19549,53 | 0,92 | 0,90 | 0,05 | 0,06 |

χ^2 = chi-square; df = degrees of freedom; MLR = Maximum Likelihood (Robust) estimator; AIC = Akaike Information Criterion; BIC = Bayesian Information Criterion; TLI = Tucker-Lewis Index; CFI = Comparative Fit Index; RMSEA = Root Mean Square Error of Approximation; SRMR = Standardized Root Mean Square Residual

Divergent validity

A measurement model containing the DSES and PHQ one-factor structures was specified to determine model fit (see Table 3b). As before, DSES items 13 and 14 were removed to determine divergent validity. The same error variances for the DSES items could correlate (DSES 1 and 2, DSES 4 and 5, and DSES 10 and 11). No PHQ items proved problematic, but two error variances were also allowed to correlate (PHQ 3 and 4, and PHQ 6 and 9). The subsequent measurement model showed good fit, as well as a non-significant correlation (close to 0.00) between the DSES-factor and the PHQ-factor, confirming the divergent validity of the DSES.

5. DISCUSSION

The main finding was that the unidimensional 16-item DSES had good psychometric properties and, therefore, met the criteria for validation in this group of black South African students. In determining the internal consistency reliability of the DSES, it was found that the scale in this study had a α -value of 0.85, which is comparable to a Cronbach alpha value, and could be considered as good (Raykov, 2009). This finding corresponds to reliability indices found by Underwood and Teresi (2002, 2011), ranging from 0.91 to 0.95 in three validation studies of the DSES.

In determining the factorial validity of the DSES, the one factor model of the 16-item DSES showed good statistical fit with data from this group of participants and supported the factor structure intended by Underwood and Teresi (2002), who developed the DSES. The single factor structure of the DSES has been translated (Ng et al., 2009) and used in various populations and contexts (Kimura et al., 2012; Underwood 2011).

Finally, to determine the convergent and divergent validity of the DSES, the scale had significant positive correlations with a measure of complete mental health, namely the MHC and its subscales for emotional well-being, psychological well-being, and social well-being. The DSES also had no (nil) significant correlations with a measure of symptoms of pathology, namely the PHQ-9. These findings, respectively, clearly indicated the convergent and divergent validity of the DSES in this research and correspond with those of Kimura et al. (2012), Ng et al. (2009), and Underwood (2011). The significantly positive correlations of the DSES with the MHC-complete (which is also of medium practical effect), and with the subscales measuring emotional, psychological, and social well-being, seem to indicate the relevance of the daily spiritual experience construct in the fields of psychological, spiritual, and relational well-being (Wheeler et al., 2009; Khumalo et al., 2014).

The DSES significantly positively correlates with psychological well-being; this implies that in this group of African youth, spiritual well-being contributes to experiences of self-acceptance, positive inter-personal relations, autonomy, environmental mastery, and personal growth. Different dimensions of spirituality and making use of different pathways can result in different psychological well-being outcomes. Such mechanisms – by means of which spirituality leads to well-being – would explain the dynamic interrelatedness of spirituality and well-being (Khumalo et al., 2014). Khumalo et al. (2014) found that meaning in life is one such factor that could explain the beneficial influence of spirituality on psychological well-being. Aspects such as hope, satisfaction with life, quality of life, and perceived social support have also been found as mediating factors in the spirituality-well-being relationship (Park, 2007; Steffen, 2012; Underwood, 2011).

The DSES also correlated significantly positively in this study, with emotional well-being, or the feeling good component of the MHC. Ciarrocchi and Deneke (2005) found that a daily spiritual experience was linked to improved emotional health of prisoners and, in a review study, Counted Possamai and Meade (2018) found that spirituality is beneficial for emotional well-being, because it acts as an internal locus of control in emotional regulation. Wheeler et al. (2002) argued convincingly about the role of spirituality in emotional development throughout the lifespan of the African individual, about the necessity of spirituality, and especially daily spiritual experience.

Furthermore, in this study, the DSES had a significant positive correlation with social well-being as a component of complete mental health. This implied that in this group of African students, their spiritual wellness – in the form of daily spiritual experience – contributed to them experiencing social coherence, actualisation, integration, acceptance, and social contribution (Keyes, 2006). Philosophically, this is confirmed by the views of Wheeler et al. (2002), who place spirituality at the centre of the collective (socially bounded) worldview of African people. According to their view, spirituality “tells the individual that s/he exists in and because of community” (p. 77). Through this awareness of their social connectedness, the individual has confidence in themselves, and the courage to conduct themselves within the community. In empirical research, Underwood (2002) found spirituality to be associated with perceived social support, and Kassin, Fein, and Markus (2014) cited research indicating socially constructed religious rituals that provide “a community lifeline of social support to prevent isolation and promote a safe and healthy way of life” (p. 602). Spirituality seemingly also works through features such as hope (Herth, 2001) and optimism (Pargament & Mahoney, 2009), towards social well-being.

The relationship between spirituality and positive mental health reported above, was succinctly captured by Ellison (1983, p. 332), in saying that, “if we are spiritually healthy, we will feel generally alive, purposeful, and fulfilled, but only to the extent that we are psychologically healthy as well”.

Finally, although the DSES in this study had no correlation with a measure of pathology, including symptoms of mood disorders, it could be noted that daily spiritual experiences are often included in interventions to alleviate mood disorders such as depression and anxiety (Mofidi et al., 2006; Underwood, 2011). Follow up research on such interventions showed the positive effect of DSE on mood disorders (Mofidi et al., 2006; Han & Richardson, 2010), and on physical conditions (Koenig, George, & Titus, 2004; Blumenthal et al., 2007; Fombuena et al., 2016). This study, to validate the DSES for use with a group of black South African students, found that the scale was valid for use within this context.

6. CONCLUSION

Spiritual well-being is an important part of well-being, and it is thus important that measuring instruments for it are valid and reliable. This study investigated the psychometric properties of the DSES in a black South African student context, by examining the internal consistency reliability and the criterion-related validity of the DSES. The scale has met validity criteria and proved to be psychometrically sound for research in a South African context. This indicates that the DSES is of general use in the current context as a domain-general measure of spiritual experience in daily life and can be recommended for further research in spiritual or well-being studies.

ACKNOWLEDGEMENTS

Gratitude to L.G. Underwood, Ph.D., for permission to use the DSES. Further gratitude to the 324 participants in this study. Views, findings, conclusions, and recommendations are those of the author only.

PERCEIVED OBSTACLES FACED BY SMALL AND MEDIUM-SIZED ENTERPRISES: A CROSS-COUNTRY STUDY

E.M. Rankhumise

Tshwane University of Technology, Pretoria; South Africa

ABSTRACT

It is a well-known phenomenon that small and medium-sized enterprises (SMEs) worldwide play an important role in many economies. This sector is imperative for both individuals and the nation at large. Contributions are made on two fronts: (i) for individuals, SMEs provide employment and raise the living standards of the employees and (ii) for the nation, they complement the large scale of modern sector enterprises, make use of the raw materials that otherwise would not have been used and mobilise other resources required in the process of running the business. Governments have prioritised the support of this sector, but SMEs still face numerous obstacles, notably the lack of marketing skills, lack of access to finance and problems with electricity supply. The overall purpose of the study was to explore the perceived obstacles faced by SME owner-managers in South Africa and China. The rationale for a cross-country study was to understand the experiences of SME owners and how differently the obstacles affect entrepreneurial activities in the two countries. The rationale seems to be obvious; however, the notion was that the experiences of the two countries might be different and the entrepreneurs from the two countries could yield some positive spin-offs on how SME owners manage to run their businesses successfully and grow their profits. Understanding the experiences shared by the SME owners who participated in the study could enhance and enable other or nascent entrepreneurs to overcome the obstacles. In operationalising the research, the researcher adopted a quantitative research approach that was cross-sectional in nature. Quantitative data were collected from SME owner-managers in South Africa and China. 400 questionnaires were distributed in each country, equating to 800 distributed questionnaires. Upon completion of the data collection process, 401 questionnaires were returned and usable. In managing data and their analysis, the researcher used the statistical software packages Epi-Info and Stata V15. SME owner-managers identified factors perceived to be obstacles in the running of their businesses. The findings reveal that factors such as unreliable electricity supply, lack of access to finance, as well as lack of marketing skills are obstacles for SMEs. It further emerged that lack of government agency support is a major factor, especially in South Africa where the majority of respondents believed that they did not get support from the agencies. It is strongly recommended that SME owner-managers devise effective strategies to overcome these obstacles if they anticipate succeeding in pursuing their businesses.

Keywords: China, constraints, economic growth, employment, obstacles, SMEs, South Africa

INTRODUCTION

It is a well-known phenomenon that small and medium-sized enterprises (SMEs) worldwide play an important role in many economies. This sector is imperative for both individuals and the nation at large. Contributions are made on two fronts (Kamunge, Njeru, & Tirimba, 2014): (i) for individuals, SMEs provide employment and raise the living standards of the employees and (ii)

for the nation, they complement the large scale of modern sector enterprises, make use of the raw materials that would otherwise not have been used and mobilise other resources required in the process of running the business. SMEs contribute to economic growth, job creation and poverty alleviation (Abebaw, Mulate, & Nigussie, 2018; Sitharam & Hoque, 2016). Bilal and Mqbal (2015) argue that SMEs play a pivotal role in the growth and development of any economy. As a result of contributions made to individuals through employment and to the nation, SMEs create a significant amount of revenue in the country, which increases the GDP. In order to ensure the sustainability of the contributions made, it is important to support them so that they are successful in their endeavours.

Though the contributions of small businesses to economic development are generally acknowledged, these businesses face many challenges and obstacles that limit the prospects of their long-term survival (Abebaw et al., 2018). Scholars such as Bilal and Mqbal (2015) posit that SMEs are faced with an array of challenges characterised by difficulty to acquire finance, heavy costs of compliance, lack of marketing skills and lack of information. Kuratko and Hodgetts (1995) and Noshad, Amjad, Shafiq and Gillani (2019) share similar sentiments in their studies in which they identify the most common obstacles as technical competence, tolerance of failure, internal locus of control, human relations and high achievement drive. Shakantu and Shakantu (2007) and Nkwabi and Mboya (2019) maintain that SMEs face many constraints in the pursuit of their businesses, for instance, lack of skills of employees, political constraints, inadequate technology, lack of equipment, lack of infrastructure, shortage of collateral, corruption and difficulty getting raw materials. These factors seem to hamper the success of businesses and therefore it becomes important for SMEs to have strategies to overcome these types of obstacles. The purpose of this study was to explore the perceived obstacles faced by SMEs in South Africa and China. The choice of these countries was aimed at understanding the importance of converging and diverging peculiarities of entrepreneurship drive and challenges. South Africa and China have very wide economic variations (Rankhumise & Masilo, 2017) and this study aimed at unravelling different challenges faced by the SMEs in these countries. Considering that China has developed substantially in terms of entrepreneurial activities, South Africa can learn a great deal from Chinese practices. This is congruent with what Ahlstrom and Ding (2014) say, namely that it is essential to understand entrepreneurship in China and transfer that experience to other developing countries on how to remove the obstacles and improve business operations. It was therefore vital to understand how differently the obstacles affect entrepreneurial activities in the two countries.

LITERATURE REVIEW

Worldwide, scholars have presented several issues pertaining to the obstacles experienced by SMEs. Quite a few of these studies rank the SME obstacles in terms of their impact on business operations (Rahman, Yaacob, & Radzi, 2016). Scholars such as Ramukumba (2014) argue that SMEs in South Africa face some challenges, such as lack of managerial skills, problems in obtaining finance and credit, access to markets, appropriate technology and support for the role they play in economic development. Similarly, further obstacles experienced include lack of enabling environments and procedural knowledge and requirements on how funding can be obtained. Further studies (Ensari & Karabay, 2014) found that several factors such as shortage of resources and lack of managerial expertise and technical competencies of the owners are believed to be obstacles to the success of SMEs. It was also found that for businesses to flourish, the

business environment needs to be conducive to their business operations (Maye, 2014). Other key findings are lack of skilled staff, burdensome regulations, local economic conditions, lack of finance and heavy labour cost. Previously South Africa's labour force was dominated by unionised employees and the unions had negotiation rights for better wages for their constituencies. This situation has since changed due to the decline in the membership of unions. Due to high labour costs and the minimum wage determination in both countries, SMEs are unable to employ many job seekers.

Rankhumise and Masilo (2017) maintain that SMEs do not always succeed in attempting to secure start-up funding, and as such, they end up getting start-up capital from their savings and with friends' assistance. According to Hogan, Hudson and Drnevich (2016), securing start-up funding to establish and grow an entrepreneurial venture through its developmental stages is the major obstacle for start-up firms and it impacts their success and substance.

Mnisi and Rankhumise (2015) in their study identified several internal factors that serve as obstacles for businesses to succeed:

- *Lack of managerial skills* – Managerial skills are important in running and managing a business successfully. Owner-managers need to have experienced insight in planning, conceptual skills, communication and decision-making skills. Accordingly, managerial competencies could have a positive influence on the performance of SMEs, as advocated by Sitharam and Hoque (2016). In essence, managerial skills have to do with the manager's ability to execute the functions of the organisation, i.e. planning, organising, leading and control.
- *Lack of functional skills* – These skills are critical for the success of the business. Important to note is that SME owners should be able to understand the functions of the enterprise, i.e. administration, marketing, financial and human resources and so forth. SME owners should be able to plan properly for the business activities and to organise the resources required in the business.
- *Poor planning* – Kambwale, Chisoro and Karodia (2015) and other scholars attest that lack of planning is a major obstacle that may lead to business failure. Notably, in all aspects of business, planning plays a fundamental role in providing direction on how the planned activities would be achieved and the resources required to accomplish the activities.

Lack of proper infrastructure is another obstacle identified by Kinyua (2014) as a factor that could hamper SMEs in carrying out their activities successfully. Importantly, a spatial planning approach could ensure that there is an efficient use of available infrastructure and other resources.

Meyer and Meyer (2017) claim that there are major challenges faced by SMEs which have an impact on SME development in South Africa:

- *Lack of access to finance and credit resources* – In this regard, many businesses struggle to secure finance and in many cases, if not all, the owners use their savings to start their businesses. This is because commercial banks require collateral security for the loans (Bilal & Mqbali, 2015).
- *Business management skills* – For businesses to prosper in their activities, business owners need to be well versed in the management of SMEs. These relate to skills, such as communication, problem-solving and decision-making, and could assist SME owners in understanding how to start, manage and run a business venture.

- *Poor infrastructure* – Access to proper infrastructure is pivotal for the success of the business. This relates to physical property, transport, water, electricity and roads (Meyer & Meyer, 2017). In a similar vein, the Bureau for Economic Research (BER) (2016) indicates that lack of access to physical infrastructure is a key obstacle to business growth and adds to the costs of doing business. Small businesses in Gauteng are struggling to find physical space in which to operate their business, and in the North-West, businesses experience power supply interruptions (BER, 2016).

Bushe (2019) also shares similar sentiments that SME owners would run their businesses successfully if the infrastructure in the economy supported their endeavours instead of hampering their efforts.

Based on the above, it is imperative to address the identified challenges by SME owner-managers. Notably, some of these issues should have been identified at the inception of the business and should have been addressed accordingly.

Muriithi (2017) conducted a study among African SMEs and found that the following were some of the factors perceived as hindrances to the success of the businesses:

- *Electricity supply* – The supply of electricity to SMEs is key for their operations. A lack of electricity supply can prevent the business from operating at optimal capacity. There is either no electricity supply and/or there is continuous disruption due to load shedding, especially in South Africa. Arguably, to run a 21st century business, it is important to have a steady electricity supply in order to operate optimally, regardless of the type of business.
- *Poor management* – Worldwide, a major challenge facing SMEs is poor management. This is because some SME owners or managers lack managerial expertise, which will ultimately affect operations. Poor management could be as a result of lack of education and training. With poor or no management, SMEs are likely to experience challenges, which will impact negatively on the success of the business in terms of managing the affairs of the business and money generated.
- *Competency and capability* – These are associated with the owners' knowledge, skills and experience. When these owners are lacking in these aspects, they may struggle to operate their businesses successfully. To this end, Fatoki and Gware (2010) explain that “management capacities are sets of knowledge, skills and competencies that can make the small firm more efficient”. The reason for the continued lack of the aforementioned elements is that most SME owners start a business out of desperation and as such, they are unable to plan and even mobilise resources effectively.

Although China's labour force is not unionised and their cheaper labour has been harmonised through the national and regional authorities, the cost of labour has become more expensive (Ling, Yusof, Mahmood, & Soon, 2014) as well. SMEs in China have significant potential to create employment opportunities because of labour-intensive industries (Yang, 2015; Luo *et al.*, 2009). Luo *et al.* (2009) argue that the majority of firms enjoy a significant labour cost and this has been a driving force for many sectors in China. This notion has enabled SME owners to employ a sizable number of employees, decreasing the number of unemployed citizens.

Furthermore, Yang (2015) posits that Chinese SMEs, under a new normal economy, experience obstacles such as innovation in capabilities, which means that they need to focus mostly on product

renewals and reduce production costs. The new normal economy is a concept developed by President Xi Jinping which denotes the following: (i) Slowing down the speed of growth, from very high speed to medium-high speed, (ii) upgrading the structure of the economy and (iii) increasing demand for the service industry. Another obstacle is financing, and this persists despite the efforts made by the Chinese government to implement favourable loan and taxation policies to aid the SMEs.

Other studies have identified some obstacles hampering the success of SMEs worldwide. For instance, Ahlstrom and Ding (2014) point out that Chinese entrepreneurs face critical challenges such as limited access to credit. Cong (2009) asserts that very few of China's millions of SMEs obtain formal financing. Lam and Liu (2020) in their study similarly found that SMEs in China face access to financing as a major problem. It emerged that access to finance differs from one region to another; for instance, firms in large cities tend to have better financial access than those in smaller cities. Muriithi (2017) agrees that the growth of SMEs in Africa needs an adequate supply of capital, and this seems to be a major hindrance to SMEs' survival and possible prosperity. Rankhumise and Masilo (2017) concur with the aforementioned scholars and say that when applying for loans, SMEs are not always successful. Some of the reasons provided include lack of collateral and lack of identification of the market. It should further be emphasised that banks in South Africa are not convinced to invest in SMEs, and the same applies in China (Yang, 2015).

Noshad *et al.* (2019) also identify some obstacles hindering the prosperity of SMEs, one being insufficient and poor infrastructure which could impact SMEs, especially in the BRICS countries with specific emphasis on Chinese SME owners. In this regard, most profit-seeking businesses are restricted due to inadequate infrastructure. Ordinarily, poor infrastructure could include bad road conditions, lack of electricity and lack of suitable workplace.

RESEARCH DESIGN AND METHODOLOGY

In operationalising the research, the researcher adopted a quantitative research approach which was cross-sectional in nature (Collis & Hussey, 2014). In a cross-sectional study, researchers take surveys at a single point in time (Letsoalo, 2017). In South Africa, the researcher personally distributed the questionnaires to the participants. In China, the questionnaires were distributed by the coordinators using QR (WeChat), which is an electronic means used throughout China for surveys. The sample consisted of SME owner-managers in China and South Africa. The study was conducted in Limpopo and Mpumalanga provinces of South Africa, and in Xian and Shanghai in China. China has over 40 million SMEs and South Africa over 25 million. Therefore, the sample size of the SMEs was restricted to 800. The reason for focusing on 800 was financial constraints. A total of 400 structured questionnaires were distributed in each country by fieldworkers, totalling 800 distributed questionnaires (De Vos, Strydom, Fouché, & Delport, 2011). A convenience sampling technique was used for the study since it was not possible to include every SME owner-manager with the almost infinite population (Etikan, Musa, & Alkassim, 2015). This non-random sampling included the members of the target population that met certain practical criteria, for instance accessibility, geographical proximity, willingness to participate in the study and availability at a given time. The research collaborators in China had to make appointments with the SME owner-managers and similar arrangements were made in South Africa. A total of 401

questionnaires were returned that were usable, representing a response rate of 50.1%. In the process of managing data, the researcher used the Epi-Info statistical software package for data capturing. This software was regarded as appropriate for capturing and managing data due to its functionalities. It should further be noted that a number of data capturing programs exist, inter alia Notepad and Excel. It was the researcher’s choice to use the aforesaid software and Stata V15 was used for data analysis. Stata was preferred to other statistical analysis software because of its functionalities such as a version-control system enabling syntax to be saved and the analyst being able to check the theory behind the results before producing the final statistical report. Both descriptive and inferential statistics were computed. For internal consistencies of the questionnaire, Cronbach’s alpha was used (Tavakol & Dennick, 2011) and a cut-off point of 0.7 was taken as the baseline. Pearson’s chi-square test was used to test for association. The interpretation of the results was performed at a 0.05 error rate. In other words, the association was declared significant if the observed p-value was less than a nominal 0.05.

RESULTS AND DISCUSSIONS

Sample realisation

The results of the study are presented as aggregate proportions of the two countries and therefore only overall results for each variable per country are presented as reflected in Table 1 below. Data were collected from 401 respondents from South Africa and China. Most of the respondents (266; 66.33%) were from South Africa and China accounted for 135 (33.67%). Most of the businesses were owned by males: South Africa 59.02% and China 62.22%. The results show that most of the sampled businesses provided services, with South Africa at 52.65% and China at 40%. This was followed by retailers: 26.14% from South Africa and 25.93% from China. Businesses in manufacturing and other sectors were 9.85% and 11.36%, respectively, in South Africa and 13.33% and 20.74%, respectively, in China.

In terms of source of capital, it emerged that most of the SME owner-managers used their savings. The highest level of personal savings (71.97%) was found in South Africa compared to 51.85% in China. 21.97% of South African SMEs and 15.56% of Chinese SMEs used family investments. A low proportion of the businesses were able to acquire capital from the bank: a mere 3.79% for South African SMEs and 19.26% for Chinese SMEs. Government grants and other sources ranked the lowest, with only 0.38% for South African SMEs and 1.48% for Chinese SMEs. The level of support is therefore very low in each country in terms of acquiring capital from banks. Lastly, South African (1.89%) and Chinese (11.85%) SME owner-managers received finance from other sources. The findings reveal that in both countries, most of the respondents had no prior experience of how to run a business, as reflected in Table 1. The results suggest that this aspect was similar for both countries, 67.70% for South Africa and 66.15% for China.

Table 1: Characteristics of SME owner-managers

| No | 174 | 67.70 | 86 | 66.15 |
| Yes | 83 | 32.30 | 44 | 33.85 |
| | 257 | 100 | 130 | 100 |

Some of the respondents did not complete the questionnaire in its entirety. These missing values (less than 10%) were all included in the data analysis as zeros (Ploum, Blok, Lans, & Omta, 2018).

To assess scale reliability, Cronbach's alpha was computed to test for internal consistency. A cut-off point of 0.7 has been used as an acceptable value by various scholars (Hair, Black, Babin, & Anderson, 2010; Lance, Butts, & Michels, 2006).

It is noticeable from Table 2 that most of the South African respondents (76.09%) indicated that access to finance was a major obstacle to business success (China: 23.91%). This indicates that there is a significant association between the respondents from the two countries ($p < 0.0001$). In other words, the respondents of the two countries had significantly differing views on access to finance as an obstacle to business prosperity. This confirms what scholars such as Lam and Liu (2020) found in their study. It could be deduced that access to finance is seen as a challenge to the prosperity of SMEs, particularly in South Africa.

It was further revealed that access to electricity was not regarded as an obstacle, with South Africa at 59.31% and China at 40.69%. Therefore, there was a significant association ($p = 0.004$) between the participants in the two countries regarding access to electricity. Respondents had different views regarding access to electricity as an obstacle to the running of the business. This finding is contrary to what Noshad *et al.* (2019) found, namely that ease of access to electricity has a negative effect on the performance of businesses.

The respondents from both countries perceived the lack of equipment as a minor obstacle to the success of their businesses. There is a significant association ($p = 0.001$) between the respondents, with more South African respondents (67.42%) considering the lack of equipment as a minor obstacle than Chinese respondents (32.58%). The fact that lack of equipment was regarded as a minor obstacle could be a result of the types of business activities performed by the businesses surveyed, i.e. the majority (48.37%) of the businesses surveyed focused on service.

Table 2: Test of association by country and perceived business obstacles

| Item | Access to finance | | Access to electricity | | Lack of equipment | | Access to information | |

The majority of the South African SMEs (73.08%) did not perceive access to information as an obstacle to the success of the business. In China, only 26.92% felt that it was not an obstacle. Therefore, there is a significant association ($p = 0.001$) between the respondents of the two countries about access to information.

Most of the respondents from the two countries viewed finding qualified personnel as a minor obstacle, with South Africa at 61.34% and China at 38.66%. There is no significant association ($p = 0.406$) since the respondents of the two countries did not have very differing views. This could mean that there is an abundance of skills in both environments.

The respondents from both countries did not perceive political instability as an obstacle to the success of the business. There is a significant association ($p < 0.0001$) between the respondents of the two countries, with 57.42% of South Africans and 42.58% of Chinese respondents agreeing that this factor did not influence the success of the business negatively.

There is an insignificant association ($p = 0.006$) between respondents from the two countries about the regulations on SME development as an obstacle to business success, suggesting that the respondents held the same views. This means that the SME owners concurred that the regulations associated with SME development did not impede the efforts of running the business.

An insignificant association is observed between the respondents in the two countries regarding high rental costs ($p = 0.582$). A high proportion (72.22%) of South African SMEs and a small proportion (22.78%) of Chinese SMEs had similar sentiments regarding high rental costs. In other words, the SMEs in the two countries perceived high rental costs as a major obstacle that hampers the success of the business.

There are significant associations between the respondents regarding cheap import products ($p < 0.0001$) and transport costs ($p = 0.001$). In essence, the SME owners believed that cheap import products did affect the performance of their businesses.

The respondents had different perceptions of the lack of government agency support as a major obstacle to business success ($p < 0.0001$). More South Africans (80.26%) than Chinese (19.74%) believed that lack of government agency support was a major obstacle. As the Chinese SMEs did not regard the lack of government support as a problem for their respective businesses, it is imperative to have a deeper understanding of how the Chinese government is providing support to the SMEs to enable South Africa to learn from them.

The South African participants (74.56%) had a strong view that a lack of marketing skills was a major obstacle to the success of the business. Only 25.44% of Chinese participants agreed. The association in this regard is significant ($p < 0.0001$). Therefore, the respondents in the two countries had significantly differing views. This finding confirms what Mkwabi and Mboya (2019) state: that marketing skills have a negative effect on business operations.

CONCLUSIONS AND RECOMMENDATIONS

In this study, the researcher sought to identify the possible obstacles as perceived by SME owner-managers as barriers in the operation of their respective businesses. Based on the results of the analysis, it could be concluded that most South African SME owner-managers believed that access to finance was a major impediment to their businesses, but only a small margin of Chinese SMEs

iewed this factor as an obstacle. The second factor, access to electricity, was not considered an obstacle to the operation of the business by either country.

The third factor is lack of equipment, which was perceived to be a minor obstacle to the success of the business. This could be as a result of most of the SMEs surveyed being in the service industry and as such, they do not need large capital equipment outlay. The fourth factor relates to access to information and it can be concluded that this factor was regarded as an obstacle mostly by South African SMEs, whereas the Chinese SMEs did not see it as such; this varied conclusion could be due to the frequency of use of technology devices.

The fifth factor is regulations relating to SME development and it can be concluded that SME owner-managers from the two countries perceived this factor as an impediment to the success of the business. It is notable that when SME regulations do not serve as enablers for the development of SMEs, the businesses are likely to fail. This factor is evident in both countries and it is prudent for the two governments to address this matter to ensure that the regulations relating to SMEs are user-friendly and accessible.

The sixth factor regarded as an obstacle is a lack of government agency support. In this context, it is evident that the Chinese SMEs received government agency support, contrary to the South African SMEs. This could be one of the factors enabling Chinese SMEs to succeed in their respective business endeavours. The South African government could learn from what the Chinese government is doing in supporting SMEs. It is notable that South African SMEs perceived a lack of government support as a major obstacle compared to the Chinese. Finally, it can be concluded that a lack of marketing skills was also perceived to be a major obstacle in the success of the SMEs. The majority of the SMEs with this view were from South Africa; Chinese SMEs did not seem to regard the lack of marketing skills as a major obstacle. It is essential that South African SMEs strive to understand how the Chinese SMEs get it right in terms of marketing skills.

As a result of the above conclusions, business owners should devise strategies to overcome the obstacles identified. By doing so, their businesses are likely to prosper. The government can also play a pivotal role in supporting businesses by making the regulations for SMEs seamless and by considering tax relief for the sector. The regulations should create a conducive environment for the operation of SMEs. The challenges experienced by entrepreneurs in these countries could hamper entrepreneurial activities and increase the failure rates of entrepreneurship. The government and its support agencies should provide the necessary support for SMEs. In addition, SME owner-managers should be creative and innovative by adopting approaches that would grow their businesses and overcome the challenges that may hamper their success.

The study had several limitations which could lead to future research directions. Firstly, a convenience sample consisting of SME owner-managers from China and South Africa was used and only 401 participated in the study. As a result, no generalisability of the findings can be claimed across the two countries. Future research should employ a larger sample that is more representative of the two countries. Secondly, the study was cross-sectional and as such, there was no opportunity to survey those who were not available on the day of data collection. Perhaps those who missed out on the survey could have provided different perspectives.

IMPLICATIONS

This study identified major obstacles to business operations which, if managed properly, may contribute to the success of the businesses. Owners should channel their efforts toward managing these impediments to ensure prosperity. Policymakers should consider the following policy implications to avert the obstacles: (i) interventions in the form of tailor-made programmes should be developed to overcome the identified challenges; (ii) a conducive environment should be created for SMEs to prosper; (iii) suitable training programmes should be provided to assist SMEs in carrying out their activities properly.

THE DETERMINANTS OF FEMALE EMPLOYMENT IN THE FORMAL AND INFORMAL SECTORS IN THE SOUTH AFRICAN LABOUR MARKET

P. Mncayi

ABSTRACT

Females remain a pivotal pillar in driving economic development. Though much has been done over the past decade to reduce equality gaps, persistent disparities remain. As part of these disparities, especially within the developing world, there has been a challenge of providing decent and quality employment opportunities for females. What determines access to these opportunities for the gender group, in this regard, has become a key focal point, both from a theoretical and policy perspective. The main objective of the study was to identify the determinants of female employment in the formal and informal sectors of the South African labour market. A quantitative approach was followed, and a cross-sectional research design was employed. Data was sourced from Statistics South Africa's fourth quarterly labour force survey (QLFS) of 2021. The sample comprised a total of 4 300 female employees who were either employed in the formal or informal sectors within the labour market. The analysis involved the use of descriptive statistics, cross-tabulations and a binary logistic regression. The results from the study showcase various factors that affect the nature of female employment within the labour market. Higher levels of education, labour market experience, as well as access to social capital seem to assist females in transitioning to formal and more stable employment. The dynamics between informal and formal sector employment, however, do seem to be made more complex taking into consideration the gendered dynamics within households, females' geographical attributes as well as their racial backgrounds. As such, the study recommends that policymakers prioritise strategies that target soft skill acquisition, reducing the time burden of domestic tasks as well provide additional support networks for the cohort. Improving the financial market inclusion of women through microcredit programmes can also help facilitate quality self-employment, while the development of the informal sector needs to be prioritised.

Keywords: Female employment; formal; informal; labour market; South Africa

1. INTRODUCTION

"Equal opportunity and equal treatment in the labour market are at the core of decent work." (Statistics South Africa (Stats SA), 2021:1). Regrettably, females, in general, remain one of the most disadvantaged in many labour markets in the world compared to their male counterparts and irrespective of their age. When they do find employment, they tend to be employed in substandard employment, with low quality and vulnerable working conditions (Beukes, Fransman, Murozvi, & Yu, 2017). According to the International Labour Organization (ILO, 2009), workers in vulnerable employment are in jobs that are not safe, and their labour rights are most likely not to

be appreciated, an essential key form of precarious work. “*The current global labour force participation rate for women is just under 47 percent, while for men, it is 72 percent; a difference of 25 percentage points, with some regions facing a gap of more than 50 percentage points.*” (ILO, 2022). The participation of females in the labour market is prevented by many aspects including non-labour market activities such as care work, which places a limitation on their income earning opportunities and therefore increases their probabilities of being in poverty. To better understand this, gender has in fact been linked with marital status or family structure, where literature reveals that a woman’s marital status influences her behaviour in the labour market (Angrave & Charlwood, 2015). Family responsibilities may constrain the labour force behaviour of married women unlike that of single women (De Anda & Sobczak, 2011). For instance, due to family and home responsibilities and even religion, some women may be forced to seek employment with fewer hours than they desire, consequently also earning less income (McKee-Ryan & Harvey, 2011).

In most cases, labour markets, especially in Africa, have a high number of underutilised labour evidenced by high unemployment, and informal and vulnerable employment (Bhorat, Naidoo & Ewinyu, 2017). For instance, the ILO’s 2017 ‘*World Employment Social Outlook*’ reports that nearly two-thirds of workers in sub-Saharan Africa are living in extreme or moderate working poverty, and South Africa is not excluded (Lilenstein, Woolard & Leibbrandt, 2016). In most cases, females are over-represented in these statistics as fuelled by labour market bias, which may push them out of formal work.

The situation is no different in South Africa with the country’s labour market offering unequal opportunities and treatment towards females, hindering them from accessing employment, let alone decent ones. The quarterly labour force survey (QLFS 4 – 2021) reports that the unemployment rate among South African females is more than 5 percent higher than that of males at 38.2 percent compared to 32.8 percent respectively (Stats SA, 2022), which suggests that chances of getting any form of employment, regardless of the sector are presently very low (Institute for Economic Justice (IEJ), 2018). Even though many policies have strived to increase the participation of females in the labour market, thereby allowing females to achieve economic independence, the issue of poverty has continued to be female (Pearce, 1978; Twerefou, Senadza & Owusu-Afriyie, 2014; Mdluli-Maziya, 2021). The aim of this paper is to analyse the determinants of female employment in the formal and informal sectors in the South African labour market. It is important to have an understanding of the kinds of jobs that female workers are in and to know which factors fuel their employment, especially in the worse-off sectors (i.e., informal sector), as decent employment is an essential prerequisite for alleviating poverty since economic growth and income transfers alone are not sufficient (ILO, 2016a).

2. LITERATURE REVIEW

2.1 Theorising formal and informal sector employment

One of the assumptions of the perfect competitive model is that competition exists in a labour market. However, this does not mean any worker can work in any job they want, as there are certain factors that prevent that from happening. Although some researchers believed that most jobs are open to competition, others (Loveridge & Mok, 1979) believed otherwise. In fact, the

widespread thinking was that there is a definite division in the labour market which averts certain workers from leaving their jobs to work in other sectors. While the neoclassical theory was based on the idea that individuals find work and therefore receive rewards based on their human capital, the segmented labour market theory, on the contrary, contends that labour markets are not distinct competitive markets, however, they are made out of an assortment of not so related fragments where rewards to human capital vary due to institutional obstacles that prevent equal benefiting from education and training (Leontaridi, 1998; Eurofound, 2019).

Accordingly, these factors keep certain individuals from adequately competing for jobs in the other sector (Kaufman & Hotchkiss, 1999). Some of these barriers include individual human capital, discriminative factors such as gender and geographical limitations, among others. These ideas were derived from the institutional school of thought, which is the main rival to the neoclassical school of thought. The core premise of the labour market segmentation theory is that the economy has multiple, distinct labour markets in which working conditions, wage bargains, and job stability vary analytically. More specifically, and according to Wachter (1974), the dual labour market theory rests on three general hypotheses. Firstly, the economy contains two sectors, a primary sector, which pays high compensation and a secondary sector, which is confined to low wages. Secondly, the important difference for economic analysis is between good and bad jobs rather than between skilled and unskilled workers. Thirdly, workers restricted to the secondary sector experience a great deal of employment instability, frequently move between jobs, and are constantly in and out of unemployment.

These markets can also be classified as the formal and informal sectors (Golub & Hayat, 2015), inclusive of skilled and unskilled labour, which allows skilled workers to work in unskilled jobs or the core and the periphery economy. The primary sector has good jobs characterised by high wages, promotion possibilities and other durable attributes that make up the primary sector of the dual economy, while bad jobs compose the secondary sector (Uys & Blaauw, 2006). Another important aspect in this sector is the presence of trade unions, which ensures worker and job protection (Harrison & Sum, 1979), a missing aspect in the secondary sector.

Conversely, the secondary sector contains the worse-off members of the labour force, who are not protected from the law and have no say in any wage bargaining processes (Uys & Blaauw, 2006). Jobs assumed to be in this market are considered to be sub-optimal, associated with lower pay, shorter working hours, unstable, generally unattractive and skills underutilisation, poor working conditions, low to no job security, and few to non-existent promotion prospects (Muysken & Ter Weel, 1999). Jobs are sufficiently plentiful in this sector to employ all workers even those frozen out of the primary sector (Wachter, 1974).

2.2 Understanding formal and informal sector employment

The formal sector includes all types of work that provide regular wages and working hours, employees are protected by rights and are subject to income tax (Sumberg, Flynn, Mader, Mwaura, Oosterom, Sam-Kpakra & Shittu, 2019). Stats SA (2022) defines the informal sector as encompassing the following aspects:

- Employees working in establishments that employ fewer than five employees, who do not deduct income tax from their salaries/wages; and

- Employers, own-account workers and persons helping unpaid in their household business who are not registered for either income tax or value-added tax.

In this regard, informal employment is regarded as less secure with fewer fringe benefits (Rutkowski, 2006), weak or risky working environments and normally little compensation and output (ILO, 2017). There is an argument that informal work might be increasing somewhat because of growing globalisation. Because of expensive business start-up costs, some new entrepreneurs have now resorted to operating in the informal sector and paying workers lower wages with the aim of limiting costs (Nightingale & Wadner, 2011). The growth of the informal sector has additionally been influenced by rapid rural-urban migration patterns that have been surged by population growth. As the population grew, large numbers of people moved from rural areas to urban areas in search of improved economic opportunities.

Owing to the limited size of the formal sector, unskilled labour that could not get absorbed into the sector because of things like a lack of demand engages in any activity, even meagre work that they can find to survive (Portes & Schauffler, 1993). This is explained by the theory of modernisation, which suggests that informal sector expansions are a transitory side-effect of migrant movements of unskilful labour have been as a result of rapid urban industrialisation (Despres, 1988). According to the ILO (2017), the informal sector is a symptom of underdevelopment, underemployment and poverty. Nightingale and Wander (2011) and Horemans, Marx and Nolan (2016) contend that the poor, who work fundamentally in these types of employment, may find it significantly more difficult than those in formal employment earning low wages to lift themselves and their families out of poverty through work alone since these kinds of work arrangements are primarily characterised by lower wages and even lower likelihood for wage increases. These kinds of work offer the plausibility to hire and fire (De Stefano, 2016).

In the informal sector, we also find precarious work, which from the worker's perspective, is employment characterised by uncertainty, unpredictability, and riskiness (Kalleberg, 2009). Broadly, precariousness in employment refers to employment physiognomies that comprise insecurity, such as inadequate levels of regulatory security, low incomes, high job insecurity and very poor worker control over working conditions, wages and hours (Vosko, 2010). Informal employment presents a number of economic disadvantages in the sense that those in informal employment do not pay income tax, which may rob the economy of potential tax revenue that would have otherwise been earned (Mncayi, 2020). Be that as it may, some studies (*see* IEJ 2018; Cichello & Rogan 2018) point out the many positive contributions that come from the informal sector, such as the fact that it helps to alleviate poverty and even though the income received by those employed in the sector is comparably low, collectively they make a significant contribution to a country's gross domestic product (GDP). Labour market outcomes for women remain poor and have always been even though gender gaps in education and labour market have been on a continual decline (OECD, 2017).

2.3 Gender and informal and formal sector employment in South Africa

Globally – in developed, emerging and developing countries – informal work is a greater source of employment for males (63%) than for females (58%); however, the same cannot be said about Africa's low and lower-middle income countries, where approximately 90 percent of all employed females are in informal work (ILO, 2018a). Even though South Africa's picture mirrors the global

picture, research proves that females are the most vulnerable group over males in the labour market (ILO, 2018b). They face more negative employment outcomes, and they are most likely to be in poverty despite them being more educated than their male counterparts. The problems begin at an early age, where, for young females, the transition to adulthood can be a solitary one as they navigate societal standards that tend to limit their development and employment choices (Fox *et al.*, 2016) and this is especially true in Africa. In Mozambique, for instance, the burden of household care and the lack of water supply has implied that females, relative to males, particularly in rural areas, have fewer hours for income-generating activities such as employment overall affecting their labour force participation (World Bank, 2012). With females in South Africa already experiencing very low labour force participation rates compared to their male counterparts, many may find themselves at the brink of informal work. Unfortunately, many people in informal work are in low-skilled jobs, unprotected from low wages, long working hours and social security, and also exposed to insufficient training prospects (ILO, 2016b). Figure 1 (a & b) shows changes in employment within the formal and inform sectors. It should be noted that South Africa’s informal sector constitutes about 4.5 million workers (Rogan & Skinner, 2017).

Figure 1(a): Changes in formal sector employment (Q4 2013 – Q4 2021)

Source: Stats SA (2022)

Figure 1(b): Changes in informal sector employment (Q4 2013 – Q4 2021)

Source: Stats SA (2022)

From the two figures above, the amount of employment created in the informal sector has for most of the years exceeded those created in the formal sector, although the paradox is that during periods of economic contraction, more jobs are being shed in the latter sector compared to the former. The fourth quarterly labour force survey of 2021 shows many wide disparities when it comes to both males and females. For instance, between 2020 and 2021, there was approximately an 8 percent decline in the number of females employed in the formal sector compared to 6.2 percent for males. The unemployment rates in the informal sector in the same period showed an increase in the number of males employed at 7 percent compared to 1.5 percent for females. Figure 2 below shows that males constitute a large portion of those employed in both the formal and informal sectors compared to females.

***employment is in non-agricultural sector*

Figure 2: Formal and informal sector employment by gender (2008-2021)

Source: Easy Data, Quantec (2022)

Despite the trends in Figure 2, the truth of the matter is that female workers often experience negative employment outcomes and even if they are employed, according to findings of Branson, De Lannoy and Brynde (2019:3), they are most likely to face substantial hardships in the form of unstable, irregular and low-paid-type of employment, depriving them of employment security. This is supported by other important statistics as indicated in Figure 3.

Figure 3: Unemployment, labour absorption and labour force statistics (2008-2021)

Source: Stats SA (2022)

From Figure 3, females remain the most vulnerable group in the South African labour market where they encounter high unemployment rates and low employment levels (Bhorat *et al.*, 2017). The gender gap in unemployment remains wide but has narrowed slightly with the unemployment rate for males increasing more rapidly than for females (DPRU, 2017; Stats SA, 2019). According

to the ‘2018 Labour Market Dynamics’ report, females in the labour force have attained higher levels of education than young males (Stats SA, 2020), but undeniably, males still have a distinctive benefit in finding work in contrast to females (Mlatsheni & Ranchhod, 2017). The reality is that many females are not investing in and acquiring relevant skills and experience needed by the labour market, which negatively affects their employment prospects (Branson *et al.*, 2019). In the ‘A Survey of Time Use’, Stats SA (2013) found large gender gaps with regard to time on non-income-generating activities such as care work. The report indicates that South African females spend three hours and 15 minutes on household care, which is more than their male counterparts spend which is just one hour and 28 minutes. Such instances are supportive of the low labour force participation rates that females encounter compared to males. Females are losing hours that they could have used on income-generating activities or searching for employment on unpaid care work. These continual disparities between males and females are one of the factors indicating that much work still needs to be made before females can achieve equality in the workplace (Department of Labour, 2017, p. 24). The next section discusses the methodology employed in the study.

3. METHODOLOGY

3.1 Research objective and design

The major objective of the inquiry was to identify the main determinants affecting female employment within the formal and informal sectors of the South African labour market. By doing so, the study utilised a quantitative approach. Secondary cross-sectional data was collected from the fourth quarterly labour force survey (QLFS) of 2021 from Statistics South Africa. Furthermore, the study employed a positivist research paradigm to serve as the philosophical base of the inquiry. By using the QLFS data, the sample was extracted using the criteria that all participants were female and either employed in the formal or informal sectors of the labour market. The final sample size and therefore comprised a total of 4 300 employed women, residing across all nine provinces of the country.

3.2 Data analysis and model specification

Subsequent to capturing the data, coding and analysis ensued. This included the use of the statistical package for social sciences (SPSS) software, version 27. The first step in the analysis comprised the use of descriptive techniques such as frequency and percentage distributions to provide a demographic overview of the sample. Thereafter, the study made use of a binary logistic regression. This particular model was used to identify the prominent determinants of female labour force participants’ likelihood of either being employed in the formal or informal sector. In line with this approach, the literature review in the previous section, shows that there are several factors that have been associated with the cohort’s employment classification. Table 1 below shows each of the included determinants as well as the coding criteria that have been applied to them respectively.

Table 1: Coding criteria for the identified possible determinants

| Possible determinants | Denotation | Coding criteria |
|-----------------------|-----------------------|--|
| Race | <i>Race</i> (X_1) | Categorical variable with two dummy variables created. Here 1 = black and 0 = otherwise; 1 = Other races and 0 = otherwise. Being white was used as the reference group. |

| Possible determinants | Denotation | Coding criteria |
|-----------------------|-------------|--|
| Marital status | $MS (X_2)$ | Dichotomous variable. 1 = Married or living with a partner; 0 = not married or living alone. |
| Age | $Age (X_3)$ | Categorical variable. A total of three dummy variables were created. Here 1 = 15 – 24 years and 0 = otherwise; 1 = 25 – 34 years and 0 = otherwise; 1 = 35 – 50 years and 0 = otherwise. Being older than 50 here was used as the reference group. |
| Geography | $Geo (X_4)$ | Dichotomous variable. 1 = residing in an urban area and 0 = residing in a rural area. |
| Education level | $EDL (X_5)$ | Categorical variable with three dummy variables created. Here 1 = primary or lower and 0 = otherwise; 1 = secondary education and 0 = otherwise; 1 = post-secondary / technical training and 0 = otherwise. In this instance tertiary education was used as the reference group. |
| Non-market activities | $NMA (X_6)$ | Dichotomous variable. Here 1 = being involved in at least 1 non-market activity and 0 = not being involved in any non-market activities. |

Source: Author’s own compilation

In light of these determinants, and the fact that a dichotomous outcome was selected for females’ employment classification, the model expresses the dependent variable in the model in equation 1 below as follows:

$$P_i = \frac{1}{1 + e^{-Z_i}} = \frac{e^z}{1 + e^z} \dots\dots\dots (1)$$

Here, P_i represents females’ employment classification and is binary either represented by 0 or 1. Additionally, within the equation, $Z_i = B_1 + B_2 X_i$. Equation 1 is known as the logistic distribution function and expresses the fact that as z moves between the values of $-\infty$ to $+\infty$ so too does the values on P_i fluctuate between 0 and 1 (Gujarati, 2004). In hindsight, this equation is linearised by incorporating an odds ratio, or in other words, the ratio of the likelihood of a success event to that of a failure for a binary dependent variable. Taking this into consideration, as well as incorporating the identified determinants into the model it can be expressed as follows:

$$L_i = \ln\left(\frac{P_i}{1 - P_i}\right) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + u_i \dots\dots\dots (2)$$

Equation 2 therefore depicts, the dependent variable (L_i) as the probability of being employed either in the formal sector (coded as 1) or the informal sector (coded as 0). As such, if females

were set to be formally employed, then $L_i = \ln\left(\frac{1}{0}\right)$ and if informally employed, $L_i = \ln\left(\frac{0}{1}\right)$. Here β_0 is indicative of the constant of the regression, $\beta_{1,2,\dots,n}$ represents the coefficients of the independent variables, while X_n shows the respective categorical variables that were included, as shown in Table 1. These pertained participants’ race, level of education, marital status, age, geography, and their involvement in non-market activities. Finally, u_i represents the error term. Upon estimating the model, the study made use of various diagnostic tests in order to determine the reliability of the results. These included the use of the Hosmer and Lemeshow goodness of fit tests as well as Cox and Snell R-Squared and the Nagelkerke R-squared. In addition to this, the study estimated variance inflator factors (VIF) as well as tolerance values for each of the

independent variables. This was done to ascertain that no multicollinearity was present between the respective regressors.

4. RESULTS AND DISCUSSION

As mentioned in the previous section, the analysis comprises two steps. The first of these withholds a descriptive analysis on the demographic and socio-economic background of the sample. Results for the analysis are reported in Table 2 below. Distributions with regard to the province of residence show that participants from all nine provinces in the country were included with Gauteng boasting the largest share (19.7%) closely followed by Kwazulu-Natal (17.3%). In addition to this, considering the racial composition, the distribution showed that 81.6 percent of the female participants were black, while nine percent were coloured, only 1.6 percent indicated that they were of Asian or Indian descent. Table 2 further showcases the participants' distribution according to age. Results in this regard pointed to the majority of employed females between the ages of 35 to 49 years (45.3%). The distribution in this instance indicated that for either side on the age continuum, lower participation rates were evident. This is to be expected given young females' transition to the labour market, while older employees are more likely to retire (Mncayi & de Jongh, 2021). On the basis of distinguishing between formal and informal sector employment, Table 2 indicates that approximately two thirds of the sample were employed in the formal sector (67.5%). Informal sector employment comprised those employed informally (18.2%), and importantly, those within private households (14.2%).

Table 2: Demographic and socio-economic distribution of the sample participants

| Aspect | Sub-category | f (%) | Aspect | Sub-category | f (%) |
|----------------------|----------------------------|-------------|---------------------|--------------------------|-------------|
| Province | Western Cape | 506 (11.8) | Education level | Lower than primary | 85 (2.0) |
| | Eastern Cape | 556 (12.9) | | Primary | 379 (8.8) |
| | Northern Cape | 164 (3.8) | | Secondary education | 2755 (64.1) |
| | Free State | 327 (7.6) | | Post-secondary technical | 679 (15.8) |
| | KwaZulu-Natal | 746 (17.3) | Tertiary | 402 (9.3) | |
| | North-West | 208 (4.8) | Race | Black / African | 3509 (81.6) |
| | Gauteng | 849 (19.7) | | White | 334 (7.8) |
| | Mpumalanga | 459 (10.7) | | Coloured | 387 (9.0) |
| | Limpopo | 485 (11.3) | | Indian / Asian | 70 (1.6) |
| | | | | | |
| Sector of employment | Formal | 2901 (67.5) | Age | 15-24 years | 166 (3.9) |
| | Informal | 783 (18.2) | | 25-34 years | 1014 (23.6) |
| | Private households | 616 (14.3) | | 35-49 years | 1948 (45.3) |
| Marital status | Married / living together | 1732 (40.3) | | 50-64 years | 966 (22.5) |
| | Not married / living alone | 2568 (59.7) | | 65 years + | 206 (4.8) |
| Geography | Urban | 2946 (68.5) | Non-market activity | Yes | 602 (14.0) |
| | Rural | 1354 (31.5) | | No | 3698 (86.0) |

Source: Authors own compilation from Stats SA data (2021b)

In line with the aforementioned demographic characteristics, the study also sought insight into the aspects such as the marital status of the participants. This is of particular interest given the role that social capital plays in female labour force outcomes (Arosio, 2017; Azcona, Bhatt, Cole, Gammarano & Kapsos, 2020). Results from Table 2, in this instance, showed that, 40.3 percent of all participants were either married or living with a partner. Another key aspect, unique to females'

labour market outcomes is the unequal distribution of time to non-market activities such as care work (Ferant, Pesando & Nowacka, 2014; Corsi & Ilkcaracan, 2022). As such, it was important to determine the level of involvement for the participants. Results indicate that only 14 percent were involved in at least one non-market-based activity in this regard. Based on their area of residence, more participants were situated in urban areas (68.5%) compared to those in rural areas (31.5%). Finally, upon review of their education level, almost two thirds (64.1%) of all participants attributed some form of secondary education, followed by 15.8 percent who had acquired a post-secondary education. Similar distributions for those with a primary education level (8.8%) and tertiary education (9.0%) were also noted.

Ensuing with the second step in the analysis, the study sought to identify the respective determinants affecting females' employment within the formal and informal sectors in South Africa. Prior to the estimation of the results, the study made use of various diagnostic tests in order to determine whether the proposed model attributed good fit with the data. Here, both the Omnibus test of model coefficients and Hosmer and Lemeshow test were utilised. These tests use opposing null hypotheses with the former stipulating that the model used is not a good fit, while the latter contrasts this. Results for both tests are shown in Table 3. The chi-square value ($\chi^2 = 696.378$) and sig. value (0.000) for the Omnibus test as well as the values for the Hosmer and Lemeshow test ($\chi^2 = 13.552$; sig. value = 0.094) both confirm good model fit. Subsequent to the estimation of these results, VIF as well as tolerance values were estimated to determine whether there was any present multicollinearity between the included independent variables. VIF values ($max = 0.965$; $min = 0.881$) were well below the prescribed value of 2 (Kim, 2019), while tolerance values ($max = 1.178$; $min = 1.036$) were above the 0.1 threshold (Field, 2018), confirming that there was no serious concern in this regard.

Table 3: Model summary and diagnostic statistics

| Omnibus test of model coefficients | | Hosmer and Lemeshow test |
|------------------------------------|-----------------------|-----------------------------------|
| Chi-square = 696.378; sig. = 0.000 | | Chi-square = 13.552; sig. = 0.094 |
| -2log likelihood | Cox & Snell R-squared | Nagelkerke R-squared |
| 4728.809 | 0.150 | 0.209 |

Source: Authors' own compilation from Stats SA data (2021b)

After ensuring the reliability and suitability of the utilised model, the estimation was undertaken. The dependent variable was entered dichotomously with *formally employed* coded as the success factor (1), while being *informally employed* was coded as 0. In line with the motivations of Labovitz (1968) for large sample sizes, only smaller error rates (0.001 and 0.05) were considered for the chosen significance levels. In line with the aforementioned, results for the binary logistic regression are shown in Table 4 below.

Firstly, considering the results for marital status, the coefficient was negative. As not being married was used as reference group, it suggests that being married or living with a partner reduced the likelihood of being formally employed, when compared to those who were living on their own or not married. The second independent variable entered into the regression model was the age of the participants. From the results shown, younger cohorts up until the age of 49 years seem to have a higher likelihood of being employed within the formal sector when compared to those that were 65 or older. Interesting though is that this seems to diminish as these female participants age.

Nonetheless, despite these insights, *significant values* for the respective age categories and marital status were deemed not significant (significant values larger than 0.05).

Table 4: Logistic regression results for formal – informal sector employment

| | B | S.E. | Wald | df | Sig. | Exp(B) |
|---|----------|-------------|-------------|-----------|-------------|---------------|
| Married / living together | -0.016 | 0.075 | 0.045 | 1 | 0.831 | 0.984 |
| 65 years and older (reference group) | | | 13.964 | 4 | 0.007* | |
| 15-24 years | 0.495 | 0.257 | 3.695 | 1 | 0.055 | 1.640 |
| 25-34 years | 0.323 | 0.189 | 2.924 | 1 | 0.087 | 1.382 |
| 35-49 years | 0.171 | 0.181 | 0.895 | 1 | 0.344 | 1.186 |
| 50-64 years | -0.024 | 0.185 | 0.016 | 1 | 0.899 | 0.977 |
| Tertiary education (reference group) | | | 300.892 | 4 | 0.000* | |
| Lower than primary education | -3.268 | 0.350 | 87.137 | 1 | 0.000* | 0.038 |
| Primary education | -3.555 | 0.288 | 152.169 | 1 | 0.000* | 0.029 |
| Secondary education | -2.568 | 0.269 | 91.481 | 1 | 0.000* | 0.077 |
| Post-secondary education | -1.294 | 0.288 | 20.162 | 1 | 0.000* | 0.274 |
| Urban residence | 0.165 | 0.080 | 4.285 | 1 | 0.038** | 1.180 |
| White (reference group) | | | 82.036 | 2 | 0.000* | |
| Black / African | -1.216 | 0.207 | 34.371 | 1 | 0.000* | 0.296 |
| Other races | -0.198 | 0.239 | 0.682 | 1 | 0.409 | 0.821 |
| NMA involvement | -0.232 | 0.103 | 5.099 | 1 | 0.024** | 0.793 |
| Constant | 3.948 | 0.362 | 118.636 | 1 | 0.000* | 51.839 |

Note: * indicates significance at a 1% level of significance; ** indicates significance at 5% level of significance; tolerance values attributed values between 0.881 and 0.965; VIF values between 1.036 and 1.178.

Source: Authors' calculations from Stats SA (2021b)

In relation to the participants' education, results shown in Table 4 showcase that all education levels, from the lowest levels to post-secondary education coefficients, were negative and statistically significant (*at the 1% level of significance*). Given that tertiary education was used as the reference category, this points to the fact that the highest levels of education and human capital still serve as predominant drivers of stable and quality employment within the South African labour market (Mncayi, 2020; Duval, Shibata & Ji, 2021). Though other levels showed a greater likelihood to informal employment when compared to tertiary levels, this does seem to diminish, especially considering post-secondary or technical training. These findings point to the importance of providing quality post-secondary education towards improving female employment (Matenda, 2019).

For South Africa though, this has been a particular challenge, with the quality of TVET colleges under scrutiny (Mabunda, 2019; Mabunda & Frick, 2020). Scholars in this regard have pointed to the lack of decent work integrated learning (WIL) programmes offered by these institutions and the lack of adequate private sector partnership, consequently contributing to inherent skills mismatches in the labour market (Batholmeus & Pop, 2019). Another important factor as illustrated in the literature review was participants' geographic location. Results in this regard showcase a positive and statistically significant coefficient ($B = 0.165$; *sig. value* = 0.038) for females residing in urban areas. The odds ratio ($Exp(B)$) in this regard showcases that compared to those residing in rural areas, these participants were 18 percent (1.180 – 1) more likely to be formally employed. These results resonate with the impact of the proximity to quality employment opportunities and overcoming the consequent search costs (Pozarny, 2016; Litsardopolous, Saridakis & Hand, 2020).

Given the importance of race within the South African economic context (Oosthuizen, 2019) and especially in labour market outcomes (Mncayi & de Jongh, 2020), it was added as an explanatory variable in the model. Here, being white was used as the reference group. Results (shown in Table 4) indicate, in this instance, that coefficients for all other racial groups were negative suggesting that for Africans/blacks (70.4% higher likelihood) and other racial groups (Asian/Indian and coloureds; 17.9% higher likelihood), all were more likely to be informally employed compared to their white counterparts. These findings support those of Mabilo (2018). The experience of the African/black labour force, in this regard, has been ascribed to various facets, including the prolonged effect of racist policies during the apartheid era, which denied the population access to formal employment opportunities (Mashimbyi, 2021), historical disadvantages in accessing education (Mutize, 2016), as well as spatial inequalities towards acquiring formal employment (Turok, Scheba & Visagie, 2017).

Finally, as the study had a particular gender focus, it was considered significant to determine the effect of females' participation in non-market activities (NMA) on their employment outcomes. Results from Table 4, in this regard, showcase a negative (-0.232) and statistically significant coefficient (*sig. value* = 0.024). These findings support the rhetoric that the gendered burden of these activities in households contributes to the likelihood that females being situated in less stable employment positions (Hearle, Baden & Kalsi, 2019). Charmes (2019) explains that the over representation of females in activities such as care work and other household chores acts as gender-based constraints to accessing the formal labour market. Informal sector employment opportunities and their inherent flexibility in this regard offer women the ability to conciliate the additional non-market responsibilities with paid work to assist in satisfying the needs of their household members (ILO, 2018b).

5. CONCLUSION AND RECOMMENDATIONS

On the basis of the inquiry, the study highlighted the precarious position of women within the South African labour market. In comparison to their male counterparts, females face significant barriers towards securing decent employment opportunities (Stats SA, 2021b). Moreover, the current literature suggests that even when this does occur, significant wage gaps exist, with evidence pointing to widening distributions in earnings between the cohorts (Ebrahim & Lilenstein, 2018). In light of these characteristics, the study had the main aim to identify the specific determinants of female employment within the formal and informal sectors within South Africa. In doing so, several important findings emerged. Results suggest that females' ability to secure decent employment opportunities is largely dependent on their education background, geographic location and as well as their racial characteristics. This seems to be further complicated by specific gender and social norms within households. Their involvement in NMA activities in this regard seems to offset their ability to obtain formal employment opportunities, reducing their time allocation directed towards better search and matching processes within the labour market.

These findings infer significant implications towards understanding the nature of empowering and improving the position of the cohort in the labour market. While the influence of education is considered pivotal, the current system does not provide the needed skills required, condemning many to precarious employment in the informal sector (Nackerdien & Yu, 2019). Responses to these features necessitate improved quality in these programmes, especially at post-secondary

level. As such, the study recommends that policymakers prioritise strategies that target soft skill acquisition, reducing the time burden of domestic tasks as well as providing additional support networks for the cohort. Strategies from this point of view should look to improve school-leavers' practical experience with WIL initiatives that are cognisant of the specific skills demanded by the private sector. Furthermore, as the study pointed to specific gendered barriers, addressing the time burden of unpaid work should be prioritised. Strong policies in this regard should focus on addressing spatial inequalities through the provision of affordable housing, infrastructure development (water access, sanitation, transport, digital) and the provision of health guarantees. Improving financial market inclusion of women through micro-credit programmes can also help facilitate quality self-employment, while the development of the informal sector needs to be prioritised. These have shown noteworthy effects in reducing gender gaps in labour market outcomes in similar developing regions (Alonso et al., 2019).

While the aforementioned initiatives seek to facilitate the movement of women into the formal sector, the importance of the informal sector towards addressing the significant unemployment levels should not be disregarded. South Africa, in this regard, relative to similar regions, has a considerable smaller and underdeveloped informal sector (Francis & Valodia, 2020). Policy responses therefore should look to assist the so-called 'forgotten sector' with strategies tailored specifically to the informal nature of these activities, taking into consideration their unique texture and spatial interactions as well as improving finance access for business enterprises. More importantly though is that renewed interest should be afforded towards improving informal-formal sector linkages by integrating and spreading power in value chains, as well as lowering the economic concentration in the formal sector through the removal of key structural impediments for informal businesses. Notwithstanding these insights, the study did have its own limitations. This pertained to the cross-sectional nature of the dataset and a lack of insight into more local dynamics. Future studies therefore can look to more detailed insight in this regard, focusing on prolonged inquiries and understanding specific dynamics within different geographical contexts within the country.

HOW HAS ECONOMIC GLOBALISATION AFFECTED INDUSTRIALISATION IN SOUTH AFRICA? ANSWERS FROM AN ARDL APPROACH

J.J. de Jongh

North-West University, South Africa

ABSTRACT

Globalisation has had a profound impact on shaping modern economic and social life. Thought to bring with it significant benefits, especially for countries' industrialisation, the process' impact has not been uniform. No more so has this been evident than in South Africa. Characterised by its own unique trade and financial liberalisation, global integration after 1994 sparked signs of economic and social progress. Recent evidence though has pointed to an ailing manufacturing sector, with concerns surrounding premature deindustrialisation. The study's main objective was to analyse the relationship between economic globalisation and industrialisation in the South African economy. A quantitative approach through the use of secondary time series data ranging from 1990 to 2019 was employed. Two ARDL models were used to test the long-run relationships, while two ECM models were used to estimate the short-run dynamics. The results suggest that higher levels of economic globalisation increase manufacturing output in the long run. However, it seems that the process exhibits a significant negative relationship with manufacturing employment. These results show that greater economic integration does benefit the quantitative aspects of the country's industrialisation endeavours, however it does withhold consequences for the process' inclusivity and broader qualitative contribution towards the standard of living. Based on these findings, it is recommended that stakeholders adequately align industrial policy towards improving regional infrastructure and market institutions as well as the development of mutually beneficial value chains, especially across the African continent. In addition, strategies should be aimed towards enhanced industrial financing and building sound public-private relationships.

Keywords: Economic globalisation, industrialisation, econometric; ARDL, South Africa.

1. INTRODUCTION

The importance of industrialisation in facilitating structural change has been markedly expressed (Nixon, 1990; Mujeri & Mujeri, 2021). The process has become a fundamental prerequisite and cornerstone towards realizing better standards of living for societies. The role of manufacturing sectors in this regard has been unique, displaying idiosyncratic characteristics which has placed their performance as one of the leading considerations for policy makers across the globe (Pal, 2021). Their role in facilitating the development of economic structures, has been encompassed in their ability to stimulate activity across value chains, displaying unique backward and forward linkages whilst likewise withholding the capacity to increase productivity through new methods of production (ADB, 2019). In light of these characteristics, much emphasis has been placed on the process to facilitate the convergence of income levels, particularly allowing developing countries the ability to transition to a developed state (Siddiqui, 2021). As the world has become increasingly interconnected, especially over the course of the last two decades, the significance of

this process has been further advanced (Vu, 2018). General expectations from this perspective, have been directed towards the assumption that the liberalisation of trade and capital accounts would afford developing countries the ability to benefit from comparative advantages, knowledge transfers and spill-over effects, all which have become synonymous with the economic globalisation process (Rodrik, 2021). These expectations have rightly been justified, as countries such as Singapore, Taiwan and South Korea have all utilised trade and foreign investment to facilitate the drive towards industrialised states. Unfortunately, these benefits have not been shared by all, as notable dichotomies within the developing world have emerged (Hauge, 2019). Coinciding with the move towards a more globalised economic system, has been the decline in manufacturing sectors' performance, especially in most of Africa (Lopes & te Velde, 2021). These performances have arguably shed light on the associated deleterious effects which amongst others have included the effect of concentrated supply chain networks, rapid and intrusive technological changes and debilitating import penetration (Adreoni & Tregenna, 2020)

In light of these complexities, understanding the nuances between economic globalisation and industrialisation has been significantly problematic (Bianchi & Labory, 2018). No more so has this been evident than in the South African context. Whilst the country has displayed similar declines in its manufacturing sector, it has had its own unique socio-economic challenges which have largely been associated with its controversial past (Habiyaemye et al., 2022). More so, compared to other countries it has displayed an idiosyncratic economic integration which as opposed to being externally imposed, by structural adjustment programmes (SAPs) has been driven internally (de Jongh, 2019). In light of these features, evidence towards addressing the question as to how the globalisation process has affected the capability of the manufacturing sector to act as an engine of growth has been severely limited. Studies in this regard, have primarily assessed the relationship on a theoretical premise (Andreoni et al., 2021; Bell et al., 2021). Where empirical attempts have been made, these have either been marked by measurement discrepancies (using proxies for economic globalisation) or have solely focused on either quantitative (output) or qualitative (employment) aspects in isolation. In light of these shortcomings, the study seeks to add to the limited body of knowledge surrounding the South African context. In doing so, it has the primary objective to examine the relationship between economic globalisation and industrialisation within the country. The paper is structured with the following section covering the literature review. Thereafter the methodology is explained, whilst section four presents the results and discusses the findings. Finally, the paper concludes with the conclusion where the major implications are identified, and pertinent recommendations provided.

2. LITERATURE REVIEW

From a theoretical viewpoint, the process of industrialisation has been continuously highlighted as one of the underlining features characterising the development of economies (Erumban & de Vries, 2021). These arguments find themselves entrenched in the seminal works of key scholars (Lewis, 1954; Kaldor, 1967), which at the core, suggest that manufacturing sectors have unique and intricate characteristics that enable them as engines of economic growth. Their ability to accumulate comparatively high levels of capital and realising important economies of scale allow for a more effective use of resources (Moyo, 2016). Blakeslee et al. (2018) further attest that they are closely linked to the use of new technologies and embody significant spill-over effects as they hold close ties and linkages with other sectors. Taking this into account, the role of industrialisation

in enforcing structural change has been profound (Andreoni et al., 2021). Towards explaining this relationship, scholars have suggested that manufacturing sector activity has displayed an inverted U-shape formation with the level of income inherent within economies (Rowthorn & Ramaswamy, 1997). These arguments suggest that as countries move from low-income levels, manufacturing sectors are important drivers of growth as economic activity shifts from agrarian based tasks to more productive and commercialised orientated motions (Hallward-Driemeier & Nayyar, 2017). During this transition, economies are able to exploit greater specialisation of labour, enhanced diversity in production, up-skilling and learning, as well as greater levels of investment and saving, all induced through industrial development (Cruz, 2015). Though as these benefits are realised, and productivity levels increase, higher income levels are associated with a drop in the share of manufacturing activity, as service sectors gain prominence on the basis of productivity differentials (Joseph et al., 2021). From this perspective, countries are set to deindustrialise as they move into a more developed state, characterised by an advanced and enabling economic structure.

In light of the fact that most modern advanced countries achieved their structural transformation via this process, it has led to the general belief, especially among modernisation and convergence theorists, that the replication of these features would essentially allow developing countries to do the same (Simandan, 2020). Whilst these suppositions, provide notable insight, the onset of a more globalised and interconnected world has significantly augmented these dynamics. Dependency and world systems scholars argue, that as trade relationships have formed and integrated financial markets have taken up prominence, core-periphery relations within international exchanges have impeded some countries' ability to adequately industrialise (Kaya, 2010). For others though it has inferred the ability to accelerate the process (Felipe, 2019). Economic globalisation in this regard has played a fundamental role in shaping manufacturing sector performances across the globe. Thibane and Wait (2017) describe this process as one that entails the international exchange of goods, services and technology through the liberalisation of trade. Likewise, it has seen the internationalisation of financial markets, leading to a significant mobility of capital and a growing influence of multinational corporations through the establishment of global value chains (GVCs) (Erel et al., 2020).

From these perspectives, the influence of economic globalisation on the ability of economies to modernise and industrialise has been captured to some extent within the Stolper-Samuelson theorem (Rodrik, 2021). The theorem posits that as countries have integrated into the global economy, a global reorganisation of manufacturing has ensued, largely on the basis of an international division of labour (Haile et al., 2013). These views, suggest that developed countries seeking to take advantage of low-labour costs inherent within more labour-intensive structures in the developing world, have relocated their manufacturing activities as a means to shift resources to more capital intensive and high value activities (Wood, 2019). Consequently, as developing countries exploit their comparative advantages and enjoy sustained foreign investments, this induces higher levels of manufacturing output and employment (WTO, 2019).

Whilst these benefits have been evident in the success of various Southeast Asian countries over the course of the last 30 years, the reality unfortunately, has been that economic integration likewise has inferred noteworthy adverse consequences on the developing world (Joseph et al., 2021). Desai and Rudra (2019) explain that whilst low- and middle-income countries, have liberalised their trade and financial markets to take advantage of the associated benefits, they have

inadvertently exposed themselves to international price trends. In the face of low competitiveness within their domestic markets, this has inferred what various scholars have come to understand as a premature deindustrialisation (Tregenna, 2016). In contrast to the deindustrialisation experienced by already developed countries, this process is characterised by a fall of manufacturing share in GDP at much lower levels of income and far lower levels of industrial activity (Dasgupta & Singh, 2006). As a result, many of these countries have been unable to realise the associated economic benefits of the industrialisation process, so desperately required to facilitate structural change (Hajime & Hiroshi, 2019).

Taking these complex dynamics into account, understanding the influence of South Africa's economic integration on the industrialisation of the economy has proven a difficult task, especially considering the unique nuances within the country's social and economic climate (Deliotte, 2013). These pertain primarily to the country's abolishment of the apartheid regime in the early 1990s, which up until that point attributed signs of significant concentration, a lack of diversification as well as comparatively low levels of investment and productivity within the economy (Joffe et al., 1994). With the transition to a democratic state and the removal of various economic sanctions, much optimism was afforded to the manufacturing sector to act as critical facilitator in fostering structural transformation and address the triple challenges of unemployment, poverty, and inequality (Habanabakize & Mncayi, 2022). As the country liberalised its trade and embarked on its own unique economic integration, industrial policy followed suit, embodying Washington Consensus-type reforms (Zalk, 2014). The adoption of these reforms was based on the assumptions that financial and trade liberalisation would induce a more efficient allocation of capital and allow the exploitation of comparative advantages, all which would assist in developing a strong and competitive industrial base.

For the first 10 years after 1994, the adoption of these policies in managing the integration into the global economy did seem to do just that. From 1994 to 2005 manufactured exports increased by an average annual growth rate of approximately 6.7 percent, which was much higher than the preceding 2.7 percent of the prior two decades (Manuel, 2007). Although these gains were noteworthy, the sector's performance since then has been all but lacklustre (Avenyo et al., 2021). Stats SA (2021) reports that manufacturing employment as a share of the total labour force has declined from above 15 percent to below eight percent during this time. Likewise, manufacturing value added (MVA) as share of gross domestic product (GDP) has declined from highs of 15.7 percent to 11.74 percent (World Bank, 2022). Whilst these declines might suggest the transition towards an innovative and service-based economy, reflecting the needed structural transformation, this has occurred at much lower income levels compared to the already industrialised countries. For example, Rodrik (2020) reports that South Africa achieved its peak of MVA (as a % of GDP) at approximately \$5 432 GDP per capita, which compared to countries such as Italy (\$18 034), the US (\$14 765) and Spain (\$13 360) is considerably lower. Even when compared to the performance of other developing countries (*Mauritius = 1.6%; Thailand = 2.9%; India = 5.9%*), the average MVA per capita growth rate (0.5%) for the past two decades, points to the country experiencing a premature deindustrialisation (Bowden 2021).

In light of these dynamics, much attention has been afforded towards understanding the impact of the country's economic globalisation in relation to its industrialisation path. Scholars in this regard, have pointed to several considerations that might have contributed to this decline (Green, 2009;

Barnes, 2019). As the world has integrated, manufacturing sectors too have been greatly linked to global networks which has played a detrimental role in local performances. These nuances have presented themselves from both the financial and trade related aspects which have been aggravated by the country finding itself in a so-called middle-income trap (Andreoni et al., 2021). Amongst these challenges, has been the country's inability to penetrate globally concentrated manufacturing networks. Though, where they have managed to do so, engagements with GVCs have been characterised by low value-added production which has contributed to the disarticulation of local performances (Bell et al., 2021). An additional challenge is fostered around the inability of the country to keep pace with rapid technological advances, which has seen it been excluded on the basis of a lack of international competitiveness (Andreoni & Tregenna, 2020). The latter has been further exacerbated by the fact, that despite various industrial policy initiatives, the country has continued to display significant lower levels of productivity and a concerning high dependence on commodity exports (United Nations, 2018).

Taking these ambiguities into account, empirical evidence directed towards understanding the dynamics between economic globalisation and industrialisation, especially in the developing world have been limited. Additionally, in instances where studies have analysed these interrelationships, evidence has been miscellaneous. For example, Kaya (2010) through the use of a fixed effects, OLS panel regression for 64 developing countries from 1980 – 2003, using proxies (trade openness; FDI) for globalisation, suggested that trade drives industrialisation through enhancing manufacturing employment. A more recent study by Ngouhouo and Ewane (2020) in comparing these dynamics between 23 Franc using and non-Franc using African countries likewise showed the positive association of FDI and industrial activity. By means of a pooled PMG estimator, from 1990 – 2017, the findings showed that currency considerations did in fact play an important role in facilitating the influence of economic globalisation on manufacturing output. Conversely, Tamuno and Edoumiekumo (2012), by means of Johansen co-integration and VECM analysis for Nigeria from 1980 to 2008 showed that trade openness induced negative effects on industrial employment in the country. Similarly, Oduola et al. (2021) likewise showed these effects. Considering the impact of FDI on industrialisation on a panel of 43 sub-Saharan African economies for the period 1996 to 2018, through the use of a system GMM technique, the study highlights the influence of competition effects, natural resource seeking investment and the repatriation of profits as key factors driving the disintegration of industrialisation in these countries.

3. METHODOLOGY

3.1 Empirical study and data sources

Towards achieving the main objective, the study made use of a secondary time-series dataset for South Africa, with data ranging from 1990 to 2019. A total of 30 annual observations were included with data sourced from various databases. Included variables are shown in Table 1 below and comprised, both MVA (% of GDP) and manufacturing employment (MEMP) as dependent variables in the respective models. With the purpose of capturing the levels of economic globalisation, the study made use of an economic globalisation index, as developed by the KOF Swiss Economic Institute. The index serves as sub-index of a general globalisation index. It captures both trade and financial globalisation dynamics. Moreover, gross national income (GNI)

per capita and the real effective exchange rate (REER) were utilised as control variables. These were chosen on the basis of their inclusion in similar studies (Aldersen, 1997; van der Heijden, 2018) and with the purpose to account for productivity levels as well as the international price competitiveness. Subsequently, all variables used were transformed to their natural logarithms before the models were estimated.

Table 1: Variable description and data sources

| Variable | Measure | Database |
|--|---|-------------------------------------|
| Manufacturing Employment (MEMP) | Number of individuals employed in the manufacturing sector | SARB (2022) |
| Manufacturing gross value added (MGVA) | Value of manufacturing output (% of GDP) | World Bank (2022) |
| Real effective exchange rate (REER) | Real effective exchange rate index | SARB (2022) |
| Economic globalisation (ECG) | KOF globalization index ranging from 0 to 100. A high score indicates a high level of economic globalization. | KOF Swiss Economic Institute (2022) |
| Gross national income (GNI) | GNI per capita | SARB (2022) |

3.2 Econometric method of analysis and model specification

The study carried out the analysis by making use of an autoregressive distributed lag (ARDL) modelling technique as refined by Pesaran et al. (2001). This specific modelling technique was chosen on the basis of being utilised in cases where variables are integrated of different order of integration, that is either I(0) or I(1). Whilst it holds this advantage over similar modelling techniques such as Johansen and Julius' (1990) model of co-integration, it likewise has shown to provide more accurate results when used with smaller sample sizes (Haug, 2002). Given the aforementioned, two models have been employed aiming to achieve the main objective of the study and are shown as follows in equations 1 and 2 below:

$$\Delta LMEMP = \varphi_0 + \sum_{j=1}^k \eta_j \Delta LMEMP_{t-j} + \sum_{j=1}^k \alpha_j \Delta LECG_{t-j} + \sum_{j=1}^k \gamma_j \Delta LREER_{t-j} + \sum_{j=1}^k \delta_j \Delta LGNI_{t-j} + \omega_1 \Delta LMEMP_{t-1} + \omega_2 \Delta LECG_{t-1} + \omega_3 \Delta LREER_{t-1} + \omega_4 \Delta LGNI_{t-1} + \mu_t \dots \quad (1)$$

$$\Delta LMGVA = \varphi_0 + \sum_{j=1}^k \eta_j \Delta LMGVA_{t-j} + \sum_{j=1}^k \alpha_j \Delta LECG_{t-j} + \sum_{j=1}^k \gamma_j \Delta LREER_{t-j} + \sum_{j=1}^k \delta_j \Delta LGNI_{t-j} + \omega_1 \Delta LMGVA_{t-1} + \omega_2 \Delta LECG_{t-1} + \omega_3 \Delta LREER_{t-1} + \omega_4 \Delta LGNI_{t-1} + \mu_t \dots \quad (2)$$

from these equations, $\Delta LMEMP$ refers to any change sustained in the natural logarithm of manufacturing employment, $\Delta LECG$ the change sustained in the natural logarithm of economic globalization, $\Delta LREER$ the change sustained in the natural logarithm of the real effective exchange rate, $\Delta LGNI$ the change sustained in the natural logarithm of gross national income, $\Delta LMGVA$ the change sustained in the natural logarithm of manufacturing gross value-added (MVA), and μ_t the error term. The study also represented the short-run coefficients by $\eta_j, \alpha_j, \beta_j, \gamma_j, \delta_j$ while k is indicative of the number of lags included in both models. Furthermore, the long-run coefficients are expressed by $\omega_1, \omega_2 \dots \omega_n$. After the formulation of equations 1 and 2 specified above, the study subsequently formulated the following hypotheses:

Null hypotheses (H_0): No co-integration between the variables

Alternative hypotheses (H_1): Co-integration is present between the variables

The study employed a bounds testing procedure to test the hypotheses mentioned above. The bounds testing procedure calculates and compares the F-statistics to the lower- and upper-bound critical values established by the work of Pesaran et al. (2001). When the F-statistics are greater than the critical values, the null hypotheses are rejected, which infers that the variables are in fact co-integrated. Contrastingly though, in cases where the F-statistics are found to be lower than the critical values, there will be no rejection of the null hypothesis. Subsequent to this procedure, an error correction model (ECM) was estimated to determine the speed of adjustment back to equilibrium. This also allowed the determination of the short-run dynamics between the variables. For this purpose, the ECM models that were used are expressed in equations 3 and 4 respectively:

$$\Delta LMEMP = \varphi_0 + \sum_{j=1}^k \eta_j \Delta LMEMP_{t-1} + \sum_{j=1}^k \alpha_j \Delta LECG_{t-j} + \sum_{j=1}^k \gamma_j \Delta LREER_{t-j} + \sum_{j=1}^k \delta_j \Delta LGNI_{t-j} + \theta ECT_{t-1} + \mu_t \dots \dots \dots (3)$$

$$\Delta LMGVA = \varphi_0 + \sum_{j=1}^k \eta_j \Delta LMGVA_{t-1} + \sum_{j=1}^k \alpha_j \Delta LECG_{t-j} + \sum_{j=1}^k \gamma_j \Delta LREER_{t-j} + \sum_{j=1}^k \delta_j \Delta LGNI_{t-j} + \theta ECT_{t-1} + \mu_t \dots \dots \dots (4)$$

Again, from these equations, the error correction term is represented by ECT_{t-1} whilst θ represents the coefficient of the error correction term. The latter is used to indicate the speed of adjustment back to equilibrium. Based on these results, Granger (1988) infers that if there does in fact exist at least one co-integrated relationship, it implies the presence of causal relationships between the variables. As such, the study applied the Toda-Yamamoto Granger causality test using block exogeneity and Wald tests in an augmented VAR model to identify any causal relationships. Much like ARDL modelling, the model can be estimated using a mixture of different integrated variables (Toda-Yamamoto, 1995). Finally, towards ensuring the reliability of the results, various stability and diagnostic testing procedures were all carried out.

4. RESULTS AND DISCUSSION

4.1 Correlation analysis

As the first step in the analysis the study ensued by determining the nature and strength of the relationships that exist between the variables, doing so through correlation analysis. Table 2 below shows the results of the analysis. As shown, manufacturing employment seems to exhibit a significant and strong positive relationship with the real effective exchange rate (*sig. value* = 0.0012) and a weak negative relationship with gross national income per capita (*sig. value* = 0.0392). In addition to this, results show a significant and strong negative relationship between manufacturing employment and economic globalization (*sig. value* = 0.0000). Interestingly though, manufacturing gross value-added illustrated a strong positive relationship with both gross national product (*sig. value* = 0.0000) and economic globalization (*sig. value* = 0.0000)

Table 2: Correlation results for the selected variables

| Probability | LMEMP | LMGVA | LGNI | LECG | LREER |
|-------------|--------------------------|--------------------------|------------------------|--------------------------|----------------|
| | 1.0000 | | | | |
| LMEMP | ----- ----- | | | | |
| | -0.5734 | 1.0000 | | | |
| LMGVA | [-3.4294] (0.0022***) | ----- ----- | | | |
| | -0.4067 | 0.9482 | 1.0000 | | |
| LGNI | [-2.1809] (0.0392**) | [14.6233] (0.0000***) | ----- ----- | | |
| | -0.7425 | 0.7959 | 0.6448 | 1.0000 | |
| LECG | [-5.4312] (0.0000***) | [6.4406] (0.0000***) | [4.1329] (0.0004*) | ----- ----- | |
| | 0.6003 | -0.5273 | -0.3780 | -0.6430 | 1.0000 |

Note: () shows *p*-values; *** is indicative of significance at 1% level of significance, * at 5% level of significance, * at 10% level of significance.

4.2 Unit root analysis

Subsequent to the correlation analysis, the study used the Augmented Dickey-Fuller (ADF) unit root test for the purpose of determining the order of integration of the variables. This was done to ascertain if these indeed were integrated at I(0) (levels) or I(1) (first order of integration). Moreover, it served the purpose to identify if there were any variables that were integrated at the second order of integration as these would render the computed F-statistics of the bounds testing procedure invalid (Ibrahim, 2015). Table 3 below therefore accounts for the results obtained from these tests. Among the five variables used, four variables were integrated at first order, whilst only *LMEMP* was deemed stationary at levels. This therefore confirmed the absence of any variables that were integrated at I(2), and that bounds testing could proceed.

Table 3: Augmented Dickey-Fuller (ADF) unit root results

| Variable | Levels | | | | 1 st Difference | | | | I (0)/ I (1) |
|----------|-----------|---------|-------------------|-----------|----------------------------|----------|-------------------|----------|-----------------|
| | Intercept | | Trend & intercept | | Intercept | | Trend & intercept | | |
| LMEMP | -2.6722 | 0.0934* | -4.5193 | 0.0085*** | -3.1651 | 0.0350** | -3.1369 | 0.1207 | I (0) |
| LMGVA | -3.1369 | 0.1207 | -1.2451 | 0.8782 | -1.2451 | 0.8782 | -4.3586 | 0.0108** | I (1) |
| LECG | -2.6272 | 0.1016 | -2.3399 | 0.3986 | -3.1940 | 0.0329** | -3.4424 | 0.0692* | I (1) |
| LGNI | -0.9482 | 0.7536 | -0.5384 | 0.9742 | -3.0091 | 0.0483** | -3.0542 | 0.1392 | I (1) |
| LREER | -2.9606 | 0.0533* | -3.1202 | 0.1243 | -4.4277 | 0.0020 | -4.3892 | 0.0101 | I (1) |

Note: *** is indicative of significance at 1% level of significance, * at 5% level, * at 10% level.

4.3 Bounds testing for co-integration and long-run analysis

To test the impact and effects of economic globalization on South Africa's industrialisation, the study used two models. The first model employed MEMP as a dependent variable whilst the second model used MVA to quantify the industrialisation process. This was done for two reasons. Firstly, by using both employment and output measures, it provided the study with the possibility of distinguishing between the quantitative and qualitative impacts of economic globalisation on industrialisation. Secondly, by employing two different measures of industrialisation, the robustness of the analysis and its findings are enhanced. As such, the two models were estimated as ARDL 1 (1,3,3,3) and ADRL 2 (1,3,3,3) using the Schwarz information criterion (SBIC) for lag selection. After this, bounds testing was undertaken with the purpose of determining any

possible long-run relationships. The results for these tests are shown in Table 4 below with the estimated F-statistics for both Model 1 and Model 2 exceeding the upper and lower bound critical values. This confirmed the presence of co-integration for both models.

Table 4: Bounds test results for model 1 and 2

| Model | Estimated F-value | Pearson critical values | | | Presence of co-integration |
|----------------------|-------------------|-------------------------|-------------|-------------|----------------------------|
| | | Sig. level | Lower bound | Upper bound | |
| Model 1 DV: LMEMP | 5.7039 | 10% | 2.72 | 3.77 | Co-integration confirmed |
| | | 5% | 3.23 | 4.35 | |
| | | 2.5% | 3.69 | 4.89 | |
| | | 1% | 4.29 | 5.61 | |
| Model 2 DV: LMGVA | 12.4227 | 10% | 2.72 | 3.77 | Co-integration confirmed |
| | | 5% | 3.23 | 4.35 | |
| | | 2.5% | 3.69 | 4.89 | |
| | | 1% | 4.29 | 5.61 | |

Subsequent to the bounds testing, long run coefficients were estimated. Shown in Table 5 below, for Model 1, the coefficients for LECG were estimated at -0.9111, which shows the existence of a negative relationship between economic globalization and manufacturing employment levels. In other words, this implies that if the economic globalization levels increase by 1 per cent, it would lead to a 0.9111 per cent decline in manufacturing employment. Contrastingly, results for Model 2 reveals a statistically significant and positive relationship between LECG and LMGVA. The positive relationship between higher integration levels and manufacturing output are in line with the findings of Apopo and Justice (2018).

Table 5: Long-run results and coefficients

| Model | Variables | Coefficient | Std. error | t-statistics | Prob. |
|----------------------|-----------|-------------|------------|--------------|-----------|
| Model 1 DV: LMEMP | LECG | -0.911183 | 0.279636 | -3.258464 | 0.0472** |
| | LGNI | 0.700812 | 0.233552 | 3.000668 | 0.0576* |
| | LREER | -0.141084 | 0.161927 | -0.871282 | 0.4477 |
| | C | 10.878027 | 1.651900 | 6.585160 | 0.0071*** |
| Model 2 DV: LMGVA | LECG | 0.823079 | 0.531350 | 7.195028 | 0.0055*** |
| | LGNI | 0.375142 | 0.456012 | 3.015582 | 0.0570* |
| | LREER | -0.180435 | 0.390817 | -0.461687 | 0.6757 |
| | C | -5.522667 | 5.747049 | -6.181028 | 0.0085*** |

Note: *** denotes significance at 1% level; ** 5% level of significance; * 10% level of significance

Whilst the aforementioned supports the integration led industrialisation hypothesis, findings relating to the negative inducing employment effects suggest that economic globalisation does impose qualitative consequences in the long-run, primarily as a result of industrial structure change, and the ensuing demand for higher-skilled workers (Das & Ray, 2020). In addition to these results, the coefficient for LGNI in both models was positive and significant at a 10% level of significance (*model 1: p-value = 0.0576; model 2: p-value = 0.0570*).

4.4 ECM results and short-run analysis

An ECM model is conducted with aim of establishing the speed at which the variables that were found to have co-integration can adjust back to equilibrium. Table 6 illustrates the results for both model 1 and 2. It depicts the short-run coefficients and error correction terms. It can be deduced that the error correction terms for both models are negative and statistically significant, serving as a confirmation of error correction in the two co-integrating relationships. Adding to that, the ECT coefficient for Model 1 ($ECT = -0.1456$) proposes that, in one year, 14.56 per cent of the distortions

to equilibrium in manufacturing employment are eliminated. In contrast, results for Model 2 ($ECT = -0.5930$) suggests a faster rate of return to equilibrium for output, with only 1.69 ($1/|-0.5930|$) years needed for these distortions to be rectified.

Table 6: ECM results and short-run coefficients

| Model | Variables | Coefficient | Std. error | t-statistics | Prob. |
|--|----------------|-------------|------------|--------------|-----------|
| Model 1 (1,3,3,3) DV: LMEMP | D(LECG) | -0.033532 | 0.345712 | -3.442269 | 0.0374*** |
| | D (LECG (-1)) | -0.142144 | 0.271304 | -0.523929 | 0.6366 |

| CointEq (-1) | -0.593062 | 0.172864 | -3.430803 | 0.0415** | |

Note: *** denotes significance at 1% level; ** 5% level of significance; * 10% level of significance

Based on the short-run coefficients in Table 6, the results are in correspondence with those reported for the long-run. Manufacturing employment seems to have been negatively affected by economic globalization and its lagging effects. Interestingly though, is that it seems to also attribute a negative influence on manufacturing output in the short-run, which is different from the results reported for the long-run. These findings lend credence to the fact that South Africa's economic integration has contributed to a premature deindustrialisation path (Andreoni & Tregenna, 2018). Whilst this contrasts to the long-run results, it does infer significant insight. Initial integration shocks seem to offset manufacturing output through enhanced competition, primarily from low wage and technologically advanced countries (Moyo, 2020). Though as enough time passes, and adaptation occurs, the structural change (greater use of technological inputs) allows the sector to grow. This however does seem to support the concerns that these changes come at the expense of labour inputs in the long-run, holding significant consequences for employment creation (Serumaga-Zake & van der Poll, 2021).

Finally, after viewing the results between an array of control and the dependent variables employed in the study, the estimates provide evidence that confirms the expected relationships. In this regard, the REER exhibits a negative influence on both MEMP and MVA. These findings are line with those presented by Boateng (2019). Here, exchange rate movements are said to have a significant influence on the sector, given the reliance on foreign inputs for countries such as South Africa (Mlambo, 2020).

4.5 Toda-Yamamoto Granger causality analysis

Subsequent to the short run analysis, Toda-Yamamoto granger causality analysis was employed. This was done on the basis of confirmation of co-integrated relationships which inferred the possible existence of causal effects (Granger, 1988). Table 7 below provides the results of the analysis. From these estimates, it suggests that there exist uni-directional relationships between LECG and LMVA as well as LECG and LMEMP, all emanating from greater levels of economic globalisation. These results suggest that changes relating to trade and financial liberalisation instil changes in the performance of South Africa’s manufacturing sector. The linkage in this regard can be explained by the sector’s relatively large exposure to foreign competition (Avenyo et al., 2021). While relatively low-cost import penetration has directly affected employment and output, the lack of the sector’s international competitiveness has inferred indirect consequences by reducing exports (Torreggiani & Andreoni, 2019).

Table 7: Toda-Yamamoto Granger causality results

| Variable | Dependent variable | | | | |
|----------|-------------------------|-----------------------|------------------------|-------------------------|----------------------|
| | LECG | LGNI | LMGVA | LMEMP | LREER |
| LECG | ---- | 1.618540 (0.6552) | 10.83045 (0.0127**) | 15.38337 (0.0015***) | 3.402323 (0.3337) |
| LGNI | 46.69846 (0.0000***) | ---- | 0.571848 (0.9028) | 0.681251 (0.8776) | 0.808244 (0.8475) |
| LMGVA | 3.485585 (0.3226) | 6.983079 (0.0724*) | ---- | 30.52499 (0.0000***) | 1.027747 (0.7945) |
| LMEMP | 1.895115 (0.5945) | 0.909821 (0.8231) | 2.701311 (0.4400) | ---- | 2.225520 (0.5269) |
| LREER | 11.51004 (0.0093***) | 0.123215 (0.9889) | 4.484385 (0.2137) | 2.384941 (0.4964) | ---- |

Note: () shows the p-values *** denotes significance at 1% level of significance; ** 5% level of significance; * 10% level of significance

Additionally, to this, changes in economic globalisation (LECG) in turn seem to be induced by augmentations in the levels of economic growth as well as the movements in the exchange rate. Both these results can be explained by the influence of favourable domestic conditions in facilitating cross border transactions (Habanabakize, 2020).

4.6 Diagnostic and stability tests

As the final step of the analysis the study employed an array of diagnostic tests to analyse the robustness of the short-run estimates. In this regard, the study tested for normality, heteroscedasticity, autocorrelation and multicollinearity. The results of the tests are reported in Table 8. Based on these estimates, residuals for both models were found to be normally distributed, there was no serial correlation whilst the aptness of the models’ functional form was also confirmed.

Table 8: Residual diagnostics and model stability results

| Item | Test | Model 1 | | Model 2 | |
|--------------------|-----------------------|---------|----------------------|---------|----------------------|
| | | p-value | Result | p-value | Result |
| Normality | Jarque-Bera | 0.4873 | Normally Distributed | 0.6069 | Normally Distributed |
| Heteroscedasticity | Breusch-Godfrey-Pagan | 0.4742 | Homoscedastic | 0.3942 | Homoscedastic |

| Item | Test | Model 1 | | Model 2 | |
|---------------------|----------------------------|---|-------------------------|---------|-------------------------|
| | | p-value | Result | p-value | Result |
| Serial correlation | Breusch-Godfrey | 0.2701 | No serial correlation | 0.7332 | No serial correlation |
| Model specification | Ramsey RESET test | 0.4596 | Functional form correct | 0.2457 | Functional form correct |
| Multicollinearity | Variance inflation factors | VIF values minimum of 1.2889 and maximum of 2.277 for all regressors. | | | |

5. CONCLUSION AND RECOMMENDATIONS

At its centre, this study had the main objective to analyse how South Africa's industrialisation has been affected by its integration into the global economy. Economic globalisation in this regard has been an overarching feature of modern processes that have come to influence the development paths of countries world-wide. Whilst it has offered several advantages in the form of knowledge spill overs, financial market development and greater efficiency through induced competition, so too has it withheld adverse consequences. For South Africa, arguably the most influential feature has been the performance of its manufacturing sector. The study's findings from this point view suggests that like most of its middle-income counterparts, economic globalisation has contributed to the premature deindustrialisation path the country currently finds itself on. Not only does it pertain to the sector's poor performance regarding its production, but more importantly, has negatively impacted on its ability to generate employment. The latter especially withholds important qualitative implications considering the country's struggles with pervasive levels of unemployment, poverty, and inequality.

In this regard, the findings of the study point to important considerations in understanding the challenges faced towards realising the potential of the manufacturing sector as an engine of growth. Amongst these, it seems that the relationship between SA's integration and industrialisation is shaped, both by exogenous and endogenous factors underlining the economic globalisation process. Internally, these challenges have emanated from South Africa's inability to compete globally, largely on the basis of high costs of production, low productivity levels as well as a lack of diversification. From an external perspective, the associated technological demands of the globalisation process have inferred significant skill biased technological change (SBTC), which in the face of a large supply of low-skilled labour has been detrimental to the sector's performance. These difficulties have also been expressed in the integration of the sector into a growing number of GVCs. This experience has been characterised particularly by large global power relationships and asymmetries, which have reflected the core-periphery dynamics between the North and South.

Based on the aforementioned, strategies seeking to propel industrial sector activity urgently need to be prioritised. The development of a strong manufacturing sector in this regard, necessitates the improvement of the local production system itself, if structural transformation is to be achieved. This requires a push towards the diversification of activity within the sector. Moreover, given the rapid changes in new digital applications across the world, public technology intermediaries promoting innovation must be made more responsive to the demands of the global economic landscape. Industrial policy from this perspective must seek to establish integrated supply chains in the local economy with a sustainable technological footprint. The latter should be aligned with a sound strategic framework which seeks to enhance labour capabilities, technological uptake and learning. Other key policy foci must also include, better industrial financing, regional partnership

formation whilst establishing sound public-private relationships that facilitate growth coalitions along the respective local, regional and global value chains. Whilst the study provides significant insight, it is not without its own limitations. This pertained the limited timeframe and sample size, to which panel studies with regional foci could potentially offer additional insight. Moreover, based on the holistic overview of the manufacturing sector, a more detailed analysis on the specific sub-sectors could also improve the body of knowledge surrounding the economic globalisation – industrialisation nexus.

ICT ADOPTION AND POVERTY REDUCTION: A CASE OF COMESA REGION

F.M. Mateko

North-West University, South Africa

O.O. David

North-West University, South Africa

ABSTRACT

Trade can be very beneficial in diverse ways and member countries can experience diverse benefits such as increased exports, technological advancement, foreign currency generation, increased economic growth and ultimately economic development (poverty reduction). Globally, regional trading blocs such as ASEAN Economic Community and European Union have benefited through trade. However, the Common Market for Eastern and Southern Africa which has more than two decades of existence has a number of its member countries still suffering from high poverty levels. This quantitative study is aimed at examining how the Common Market for Eastern and Southern Africa can harness information and communication technology investment to alleviate the enormous poverty levels among the member states. Data were generated from the World Bank and International Telecommunication Union, for the period 1994 to 2021. A Panel Auto Regressive Distributed Lag was employed in the research. Empirical findings showed that an increase in information and communication technology will lead to an increase in the human development index in the long run thereby reducing poverty. Thus, information and communication technology positively aid in poverty reduction. It was realised that trade can lead to a decrease in poverty levels. These findings show that every expansionary activity in information and communication technology and trade in the COMESA region results in higher living standards or a higher human development index. Key policies that were suggested were, improvement in ICT policies, creation of a regional research hub, promoting increased usage in internet usage, and promoting high usage of mobile phone usage.

Keywords: Economic development; economic growth; economic integration; information and communication technology; investment; trade; poverty

1. INTRODUCTION

The Common Market for Eastern and Southern Africa (COMESA) was formed in 1994 with the main aim of promoting regional trade among the twenty-one (21) economies. The Global Competitiveness Index 4.0 (GCI 4.0) of the World Bank assesses the factors and characteristics that influence productive capacity, growth, and human development in the Fourth Industrial Revolution era and the GCI of COMESA has been low. In 2019, the COMESA region at large had a low GCI score of 49.0 and only six (6) member states were in the top 100 (COMESA, 2022). The low GCI index implies low productivity growth and the bulk of economies in the COMESA region remain plagued by dire and imminent poverty. Poverty can be defined as the complete absence of opportunities, coupled with high levels of undernourishment, hunger, illiteracy levels, lack of access to education, physical and mental diseases, and socio-economic instability (Beegle

2016). Apart from that, poverty is a multidimensional aspect and can be defined using various proxies such as access to nutritious food, shelter, water and sanitation, peace, and access to education and healthcare just to mention a few (Agboola & Balcilar 2012:1). A number of economies in the COMESA region that are still facing high levels of poverty in terms of the human development index are: Somalia with 0.42, Zambia has 0.59, Rwanda with 0.53, Sudan with 0.50, Madagascar with 0.52 as well as with Malawi 0.48 (United Nations, 2020). Apart from that the rate of information and communication technology adoption and diffusion among the COMESA region is also low. This is supported by the fact that 2% of the total population in Somalia have access to use the internet (World Bank, 2022). In Libya only 21% of the total population has access to the internet (World Bank, 2022). Apart from that, some member states of the COMESA trading block are plagued by colossal macro-economic challenges such as unemployment, high imports, and limited exports just to mention a few (Pufall, Eaton, Nyamukapa, Schur, Takaruzza, & Gregson, 2016): (Endale & Tadesse, 2020). For example, Zimbabwe exports the bulk of its raw minerals to foreign markets and gain low foreign currency due to the lack of modern technology for value beneficiation (Dzviti, Maganga & Mamina, 2020; Nyemba, Moyo, & Mbohwa, 2018).

1.1 Problem Statement

Research has shown that intra trade can yield more benefits among the trading partners (Herman, 2020). Some of the benefits can be in the form of increased productivity, improved efficiency and innovation by manufacturers, earning foreign currency, employment creation, exchange of skills just to mention a few (Geng & Kali, 2021). These benefits help to improve the quality of life or the standard of living of people. Globally, there are number of trading blocs such as European Union, North American Free Trade Agreement, Asia Pacific Economic Cooperation and ASEAN Economic Community among others. A key point to note is that robust technology is at the centre of the success of many trading blocs (Herman, 2020). Economies such as Hong Kong, South Korea and Singapore which fall under the Asia Pacific Economic Cooperation managed to record high economic growth levels as well as low poverty levels due to sound export policies, adoption and diffusion of information and communication technology (Shirley, 2014). If other trading blocs such as European Union and The Asia Pacific Economic Cooperation have harnessed information and communication technology (ICT) for enhancing regional trade and economic growth, where is the missing link in the COMESA region (Becker, Becker, Sulikowski, & Zdziebko, 2018)? The weak productive capacity in ICT is a key limiting factor that hinders meaningful growth and investment returns among affiliates of COMESA. And that negatively affects the standard of living in the economic integration. In the COMESA region economies such as Zambia, Malawi, Zimbabwe and Sudan are battling with high poverty levels (United Nations, 2020). Apart from that, in terms of ICT, the rate of usage is still very low in the COMESA region at large. For example, Rwanda, Zimbabwe, Malawi, DRC are some of the economies still lagging behind ICT wise (World Bank, 2022). This implies that, the COMESA region at large will take a long time to realise the benefits of ICT usage in the different sectors, due to the low rate of ICT usage (Awad, 2022). Thus, there is an opportunity for the region to tap into ICT and channel it towards the productive and manufacturing sectors for value beneficiation as well as enjoying myriad benefits. Some of these benefits include job creation, boosting entrepreneurship increased trade flows from the use of e-commerce just to mention but a few (Cuevas-Vargas & Parga-Montoya, 2021).

Thus, there is need for a panacea to solve the low rates of ICT usage and high poverty levels in the COMESA region. This research will examine ICT adoption and poverty reduction in the COMESA region.

Research Objectives

- To preview and describe the status of ICT and poverty in the COMESA region.
- To analyse characteristics of ICT and poverty in the COMESA region.
- To establish the relationship between ICT and poverty reduction in the COMESA region.

2. LITERATURE REVIEW

2.1 Theoretical / conceptual framework

The Neo-Classical Theory (NCT)

This theory of economic development is built on the assumption that information and communication technologies (ICTs) can help poor economies transition out of endemic poverty (Ofori, Armah, Taale, & Ofori, 2021). The Neo-Classical theory holds water especially in the case of some of the selected economies under The Asia Pacific Economic Cooperation as explained prior. The theory is germane to this research because there is a need to examine how ICT can be used by the COMESA region at large for the sole purpose of rescuing the millions of population suffering from the vicious jaws of dire and abject poverty (Masoud Asst, 2013). Other economies such as Hong Kong, and Taiwan have benefited from ICT adoption hence it will be prolific too if the COMESA region member economies experience similar benefits in form of increased economic growth and reduced poverty.

Sustainable Livelihoods Approach (SLA)

Fundamentally, the approach demonstrates how economic agents can pave way for themselves by utilizing the available resources or productive materials that they have at their disposal (Ofori et al., 2021). Thus, the SLA hinges on providing a fundamental view of poor people's financial aspects and poverty. ICTs, according to Gigler (2011), are a comprehensive set of modern assets that people can use to create an enabling environment for themselves by engaging in a variety of socio-economic activities.

ICT is incorporated into the framework as a result of this, as well as the flexibility of the SLA concept in analysing poverty vulnerability, intensity, and severity (Ofori et al., 2021). Less fortunate entrepreneurs may be able to use ICT to network or look for new contracts or business opportunities. Research has shown that 90% of Africa are entrepreneurs (African Development Bank, 2011). Therefore, those entrepreneurs falling under the COMESA region can benefit from ICT adoption for positive social impact. This theory helps to explain the supply side of ICT in line with poverty reduction.

Review of Recent Literature

Lapukeni (2015) carried out research on financial inclusion and the role of ICT in the COMESA region. The research employed dynamic panel data analysis. Research findings showed that increased use of the formal financial system and increased mobile phone penetration (a proxy for ICT development) had a positive and significant impact on intra-regional trade in COMESA

(Lapukeni, 2015). From these research findings, there is no pellucid explanation of how ICT development can be harnessed and be utilized to promote intra trade which in turn helps in poverty reduction through the multiplier effect.

Apart from that, the study used mobile phone subscriptions only as a proxy for ICT development. This research will use a composite index of ICT which will include mobile phone subscription, the internet usage as well as fixed telephone usage. This is crucial since trading in the modern world is also facilitated through internet or e-commerce platforms. This will be advantageous as ICT can be better proxied by adding the three aspects as explained (David, 2019).

Jiya, Sama and Ouedraogo (2020) researched on infrastructure, trade openness and economic transformation in the COMESA region. The study employed dynamic fixed effects methods. Research outcomes showed that COMESA member countries must implement more projects to improve and expand access to energy infrastructure, particularly electricity, and telecommunications infrastructure, in order to achieve economic transformation (Jiya et al., 2020). These research findings show that telecommunications infrastructure is key for expansion in economic activities.

However, the study emphasized the importance of project implementation, but there is no clarity on how such projects can thrive when there is no ICT adoption. The precursor to the implementation of the aforementioned projects should be robust and sophisticated ICT. Thus the current research seeks to examine how ICT can be adopted by COMESA member economies for poverty alleviation. Elbushra, Abdel Karim, & Suleiman, (2011) researched on the role of COMESA in promoting intra -regional agricultural trade between Sudan and COMESA. Research findings depicted that Sudan has the potential to increase its output from the agriculture to the COMESA region. The research further recommended increased productivity as a key to enhancing the Sudan's output. However, the research is silent on how productivity can be improved. As such there is a research gap since there is no clear transmission mechanism presented on ways of improving productivity. As such this paper seeks to examine how ICT can be used as a tool for effective poverty alleviation in the COMESA region at large. The use of ICT can be beneficial to enhance farming output due to use of modern farming machinery (Ayisi Nyarko & Kozári, 2021).

A research by Ogbuabor, Anthony-Orji, Manasseh& Orji (2020) which focused on the COMESA output connectedness with the global economy revealed that the COMESA region is most heavily influenced by the output of the USA, EU, Japan, China, Canada, Indonesia, and UK, and as a result, these countries have the capacity to propagate output shocks there (Anthony-Orji *et al* 2020). In addition, the outcomes demonstrated that COMESA's output connection with the rest of the globe is extremely significant, with a total connectedness index (TCI) of 73% (Anthony-Orji *et al* 2020). However, although the COMESA region has a high TCI it remains plagued by dire and imminent poverty and as such there is a need for a panacea for that. This research will present the solution required for COMESA to escape out of poverty and low ICT usage.

3. METHODOLOGY

This section presents the research methodology used in the study. A brief description of the variables used will be presented as well as the hypothesis.

Research Design

The study was quantitative in nature and used a PVAR techniques. Data from International Telecommunication Union and World Bank from 1992 to 2021 were used in the study.

Table 1: Summary of Data Set

| Variable | Indicator | Variable Description | Unit of measurement | Source of Data |
|----------|--------------------------------------|---|-------------------------|--|
| HDI | Human development Index | Proxy for poverty measurement which includes income per capita, access to education and long life. | Index | United Nations 2022 |
| ICT | Composite Index of Telecommunication | Principal component value of connected mobile phones, percentage of people with access to internet as well as penetration of fixed lines. | Index | Author Computation based on International Telecommunication Union (2022) |
| Le | Life expectancy | The number of years a newborn infant would live if prevailing patterns of mortality at the time of its birth were to stay the same throughout its life. | Years | World Bank (2022) |
| Trade | Trade | The sum of exports and imports of goods and services measured as a share of gross domestic product | % of GDP | World Bank (2022) |
| UNE | Unemployment | Share of the labour force that is without work but available for and seeking employment. | % of total labour force | (World Bank 2022) |

Source: Researcher’s Construct (2022)

The hypothesis is specified below:

Hypothesis

Null Hypothesis: There is no relationship between ICT adoption and poverty alleviation.

Alternative Hypothesis: There is a relationship between ICT adoption and poverty alleviation.

MODEL

The research adopted the Panel Auto Regressive Distributed Lag. This model was used in the research because it helps to depict the true causal relationship between ICT and poverty. Apart from that, it was used because it helps to reduce the chances of spurious regression, (Gholami, Sang-Vong Tom & Heshmati, 2005). The model is specified below.

$$y_t = m + \alpha_1 y_{t-1} + \beta_0 x_t + \beta_1 x_{t-1} + u_t \dots \dots \dots 1$$

Where y_t and x_t represents stationary variables which are: poverty, ICT, and development aid, α_1 denotes the coefficients for long -run relationship, β_1 represents the coefficient for short run, u_t is white noise. Poverty was measured through the Human Development Index (HDI). Independent variables in the model were: ICT, unemployment (UNE), trade and life expectancy (LE).

These variables are important as far as poverty is concerned. This is justified by the fact that all these factors have a positive impact on human welfare, for example, trade can be useful for employment creation and tax from workers and business can be used by the state in providing

public and merit goods which in turn aid to improve the living standards or reduce poverty levels *ceteris paribus* (Das & Basu Roy, 2020).

ICT was measured as a composite index that included mobile telephone subscription per 100, internet usage as well as fixed telephone subscription per 100 people. Due to data unavailability Somalia was removed from the data collection. Missing data was calculated using interpolation and extrapolation techniques as suggested by (Zou, Guo, & Chen, 2018). Diagnostics tests are going to be carried out in this study and these include tests for multicollinearity, auto-correlation and heteroskedasticity.

4. PRESENTATION OF THE RESULTS AND DATA ANALYSIS

This section seeks to present the data analysis and interpretation.

Table 2: Descriptive Statistics

| | HDI | ICT | UNE | TRADE | LE |
|-----------------------|------------|------------|------------|--------------|-----------|
| Mean | 0.5091 | 14.83 | 9.117 | 72.16 | 60.65 |
| Median | 0.4900 | 8.253 | 5.84 | 59.46 | 60.95 |
| Maximum | 0.8000 | 82.11 | 29.02 | 347.99 | 77.24 |
| Minimum | 0.1700 | 0.013 | 0.465 | 0.17 | 27.73 |
| Std. Deviation | 0.1380 | 17.37 | 7.67 | 47.98 | 9.31 |
| Skewness | 0.2312 | 1.468 | 1.09 | 3.12 | -0.31 |
| Kurtosis | 2.457 | 4.790 | 3.12 | 9.57 | 2.45 |
| Jarque-Bera | 11.84 | 275.99 | 112 | 1427 | 16.82 |

Source: Researcher's Construct (2022)

The above table shows all the variables used in the study which are: ICT= Information communication technology index, HDI = human development index, UNE= unemployment, trade and LE=life expectancy. The mean for HDI was 0.5 and the maximum value was 0.8, while the standard deviation was 0.13 and the Jarque-Bera was 11.84. ICT had a mean of 14.83 and the maximum value was 82.11. The standard deviation was 17.23 and the Jarque-Bera was 275.99. UNE had a mean of 9.11 and the maximum value was 29.02, the standard deviation was 7.67 and Jarque-Bera was 112. Trade had a mean of 72.16, maximum value of 347, the standard deviation of 47.98 and Jarque-Bera was 1427. Lastly, LE had a mean of 60.65, a maximum value of 77.24, the standard deviation of 9.31 and Jarque-Bera was 16.82.

Information and Communication Technology (1994-2021)

Figure 1: COMESA Information and Communication Technology (1994-2021)

Source: Researcher’s Construct (2022)

The above figure shows that from year 1 to year 10, bulk of the COMESA economies had low ICT index. This could be attributed to the low rate of usage of mobile phones, internet as well as fixed telephone lines. As such, the COMESA region at large experienced low ICT index in the first 10 years as the index was below 30%. From year 11 to year 20, there was a rise in the ICT index for bulk of the economies in the COMESA region. The highest recorded ICT index for some of the economies such as Mauritius and Egypt was over 50%. However, on the same period some economies such as Sudan and Zimbabwe had low ICT index of below 30%. Lastly, from year 21 to year 28, the majority of the COMESA members recorded fluctuating ICT index and only a few economies performed very well. Overall, for the period in question, the ICT index for the region was below 50%. This depicts the poor status and the characteristics of ICT in the COMESA region.

Human Development Index (1994-2021)

Figure 2: COMESA Human Development Index (1994-2021)

Source: Researcher’s Construct (2022)

Figure 2 shows the human development index trend for the COMESA region. From year 1 to year 10, bulk of the members of the COMESA region had an HDI below 0.5. This implies that these economies were experiencing poor life standards, low life expectancy as well as low per capita income. Madagascar, Djibouti and Egypt were some of the few economies that had a higher HDI value in the first 10 years. From year 11 to year 20, there was a fairly sharp increase in the HDI for the majority of the economies in the COMESA region. On average the HDI value was above 0.5. This implies that there was an improvement in the lives of people but the value of 0.5 is low which implies that the region at large is still plagued by high poverty levels. From year 21 to year 28, the region recorded a steady increase in the human development index. However, bulk of the economies had an HDI value below 0.6 and this signifies that the region still needs to address the poverty levels. Overall, it can be concluded that, the COMESA region at large recorded a fair increase in the HDI levels between 1994 and 2021 but there is evidence that poverty is still an anathema to be addressed.

Partial Correlation Analysis

The table below show the Partial Correlation Analysis

Table 3: Partial Correlation Analysis

| | HDI | ICT | UNE | TRADE | LE |
|-------|------|------|------|-------|----|
| HDI | 1 | | | | |
| ICT | 0.76 | 1 | | | |
| UNE | 0.24 | 0.13 | 1 | | |
| TRADE | 0.37 | 0.35 | 0.45 | 1 | |
| LE | 0.76 | 0.64 | 0.14 | 0.26 | 1 |

Source: Researcher’s Construct (2022)

Table 3 shows that the relationship between ICT and human development index was positive at 76% while with the relationship between UNE and HDI was positive at 24%. Trade was positively

associated with HDI at 37%. LE was positively associated with HDI at 76%. UNE and ICT were positively related at 13%. The relationship between Trade and ICT was positive at 35%. LE and ICT were positively related at 64%. The relationship between Trade and UNE was positive at 45%. LE and UNE had a positive relationship at a value of 14%. Finally, LE and Trade had a positive relationship at 26%. The rule of thumb outlines that a value above 0.75 depicts strong correlation, as such in this study LE and HDI as well as HDI and ICT were the only variables slight above 0.75 (Schober & Schwarte, 2018).

Panel Data Stationarity Results Analysis

The Levin–Lin–Chu test was used to test for stationarity. To test for stationarity in this research, the following hypothesis is used.

Null Hypothesis: Panel contains unit root.

Alternative Hypothesis: Panel does not contain unit root

Table 4: Unit root tests

| Variable | T-Statistic | Probability | Test |
|----------|-------------|-------------|----------------------------|
| ICT | -2.49 | 0.00 | 1 st difference |
| Le | -6.20 | 0.00 | Level |
| HDI | -6.29 | 0.00 | Level |
| Trade | -9.93 | 0.00 | 1 st difference |
| UNE | -1.30 | 0.00 | 1 st difference |

Source: Researcher’s Construct (2022)

The p- values of all the variables above were less than 0.05 hence it was concluded that the series was stationary. HDI and Le were stationary on level, while ICT, Trade, and were stationary after first difference.

Lag length Test

The table below shows the lag length test results.

Table 5: Lag length Test

| Lag | LogLR | LR | FPE | AIC | SC | HQ |
|-----|-----------|---------|--------|-------|-------|--------|
| 1 | -2000.87 | 7642.46 | 0.0176 | 10.15 | 10.45 | 10.27 |
| 2 | -18.51.21 | 291 | 0.0094 | 9.531 | 10.07 | 9.74 |
| 3 | -17.97.71 | 102.70 | 0.008 | 9.388 | 10.18 | 9.70 |
| 4 | -1751.10 | 88.33* | 0.007* | 9.28* | 10.32 | 9.696* |

Source: Researcher’s Construct (2022)

Table 5 shows the results of the lag length test and 4 was selected as the desirable lag in this research because it had lower values based on the Akaike information criterion.

PANEL COINTEGRATION RESULTS

Panel co-integration in this research was tested using the Johansen -Fisher Co-Integration Test. The test was performed to ascertain the long-run relationship among the variables used in the research. The hypothesis is specified below:

Null Hypothesis: There is no cointegration.

Alternative Hypothesis: There is cointegration

Below are the results for the cointegration tests.

Table 6: Panel Co-Integration Results

| Hypothesized No of Ce(s) | Fisher Stat (from trace test) | Prob | Fisher Stat (from max-Eigen test) | Prob |
|--------------------------|-------------------------------|------|-----------------------------------|------|
| None* | 1246 | 0.00 | 675.0 | 0.00 |
| At most 1 | 997.3 | 0.00 | 682.1 | 0.00 |
| At most 2 | 688.3 | 0.00 | 420.3 | 0.00 |
| At most 3 | 394.3 | 0.00 | 254.8 | 0.00 |
| At most 4 | 212.5 | 0.00 | 160.4 | 0.00 |
| At most 5 | 134.1 | 0.00 | 134.1 | 0.00 |

Source: Researcher’s construct (2022)

The above results above show that there is cointegration. This implies that there is a long-run relationship between ICT, development aid, remittances, unemployment, gross domestic product and human development index. In other words, even if in the short-run there are any shocks, there is high likelihood of a convergence of these factors in the long-run.

PANEL CAUSALITY RESULTS ANALYSIS

This section seeks to present the panel causality results analysis. The Dumitrescu and Hurlin (2012) Test was used.

This is an advanced form of Granger –causality analysis. This was used to examine the relationship between variables from the panel data.

Table 7: The Dumitrescu and Hurlin (2012) Test

| Null Hypothesis | W-Statistics | Probability |
|-------------------------------------|--------------|-------------|
| HDI does not homogenously cause ICT | 8.16 | 0.00 |
| ICT does not homogenously cause HDI | 6.63 | 9.E-16 |
| REM does not homogenously cause ICT | 5.51 | 2.E-09 |
| ICT does not homogenously cause REM | 6.02 | 4.E-12 |
| UNE does not homogenously cause ICT | 5.54 | 1.E-09 |
| ICT does not homogenously cause UNE | 8.18 | 0.00 |
| DA does not homogenously cause ICT | 4.53 | 2.E-05 |
| ICT does not homogenously cause DA | 5.68 | 2.E-10 |
| GDP does not homogenously cause ICT | 7.58 | 0.00 |
| ICT does not homogenously cause GDP | 7.34 | 0.00 |
| REM does not homogenously cause HDI | 2.92 | 0.19 |
| HDI does not homogenously cause REM | 6.13 | 9.E-13 |
| UNE does not homogenously cause HDI | 3.21 | 0.06 |
| HDI does not homogenously cause UNE | 5.15 | 8.E-08 |
| DA does not homogenously cause HDI | 3.32 | 0.04 |
| HDI does not homogenously cause DA | 4.27 | 0.00 |
| GDP does not homogenously cause HDI | 4.15 | 0.00 |
| HDI does not homogenously cause GDP | 5.81 | 6.E-11 |
| UNE does not homogenously cause REM | 79.57 | 0.00 |
| REM does not homogenously cause UNE | 12.04 | 0.00 |
| DA does not homogenously cause REM | 4.93 | 7.E-07 |
| REM does not homogenously cause DA | 4.01 | 0.00 |
| GDP does not homogenously cause REM | 4.97 | 5.E-07 |
| REM does not homogenously cause GDP | 4.21 | 0.00 |
| DA does not homogenously cause UNE | 4.01 | 0.00 |
| UNE does not homogenously cause DA | 23.67 | 0.00 |
| GDP does not homogenously cause UNE | 4.56 | 2.E-05 |
| UNE does not homogenously cause GDP | 3.27 | 0.05 |
| GDP does not homogenously cause DA | 1.13 | 0.00 |
| DA does not homogenously cause GDP | 3.90 | 0.00 |

Source: Researcher’s construct (2022)

On the first equations regarding ICT and HDI, the p-value is less than 5% for both, hence it can be concluded that the null hypothesis is rejected. HDI does homogenously cause ICT On the second equation the p value is above 5% hence it can be concluded that the null hypothesis is accepted. Overall, there is unidirectional causation between the two variables. On the second equation between REM and ICT, the p-values are above 5%, thus it can be concluded that the null hypothesis is accepted for both equations. REM does not homogenously cause ICT.

On the third equation, between UNE and ICT, on the first instance, the p value is above 5% thus the null hypothesis is accepted. On the second equation, the p-value is less than 5%, therefore ICT does homogenously cause UNE. Overall, there is unidirectional causation between the two variables. On the fourth equation between DA and ICT, the p-values are greater than 5%, thus it can be concluded that the null hypothesis is accepted for both equations. On the fifth equation between GDP and ICT, the p-values are below 5%, thus ICT does homogenously cause GDP and vice versa.

For REM and HDI, UNE and HDI the p-values are bigger than 5%, therefore it can be concluded that the null hypothesis is accepted for both equations. For DA and HDI, the p-values are below 5%, Therefore HDI does homogenously cause DA and vice-versa. For GDP and HDI, the first equation has a p-value below 5%, thus GDP does homogenously cause HDI. The second equation has a p-value greater than 5%, thus the null hypothesis is accepted. Overall, there is unidirectional causation between the two variables. For UNE and REM, the p values are below 5%, thus UNE does homogenously cause REM and vice versa. For DA and REM, the first equation has a p-value above 5%, thus it can be concluded that the null hypothesis is accepted. On the second equation, the p value is below 5%, thus, the null hypothesis is rejected. A uni-directional relationship exists between these variables.

For GDP and REM, the first equation has a p-value above 5%, thus it can be concluded that the null hypothesis is accepted. On the second equation, the p value is below 5%, thus, the null hypothesis is rejected. A uni-directional relationship exists between these variables. For DA and UNE the p values are below 5% on both equations, hence it can be concluded that DA does homogenously cause UNE. For GDP and UNE, the p value of the first equation is above 5% hence it can be concluded that the null hypothesis is accepted. However, the p value of the second equation is below 5% hence it can be concluded that the null hypothesis is rejected. On the last equations for GDP and DA, the p values are below 5% and it can be concluded that GDP does homogenously cause DA.

PANEL AUTO REGRESSIVE DISTRIBUTED LAG RESULTS

This section seeks to present the results of the Panel Auto Regressive Distributed Lag model.

Table 8: Panel Auto Regressive Distributed Lag Results: Long-run

| Variable | Coefficient | P-Value |
|-----------------|--------------------|----------------|
| ICT | 0.22 | 0.00 |
| UNE | 0.68 | 0.40 |
| TRADE | 0.64 | 0.00 |
| LE | 0.10 | 0.00 |

Source: Researcher's Construct (2022)

The results presented in Table 8 show that life expectancy, trade, and information and communication technology were significant at the 1% level. Unemployment was insignificant because their p-values were above 5% significance level.

In terms of the coefficients, a 1% increase in information and communication technology will lead to an increase in human development index by 0.22% in the long run. An increase in the human development index implies an improvement in living standards. These results conform to a priori expectations and the views of (Bohlin, Hanafizadez & Vu, 2020; Mushtaq & Bruneau, 2019). This further show a high usage of ICT will help to reduce the poverty levels in the COMESA region since there is a positive relationship between poverty and ICT. With regards to trade, a 1% increase in trade will lead to a 0.64% increase in human development index in the long-run. Lastly, a 1% increase in life expectancy will result in a 0.10% increase in the human development index in the long-run. The research findings showed that the COMESA region can effectively fight poverty through the use of ICT.

The table below shows the PARDL results for the short-run period.

Table 9: Panel Auto Regressive Distributed Lag Results: Short-run

| Variable | Coefficient | P-Value |
|----------|-------------|---------|
| HDI (-1) | -0.47 | 0.02 |
| ICT | -0.003 | 0.17 |
| UNE | -0.11 | 0.67 |
| TRADE | 0.06 | 0.05 |
| LE | 0.08 | 0.84 |

Source: Researcher's Construct (2022)

The short-run results above show that trade was statistically significant, and it had a positive coefficient. This implies that a 1% increase in trade will lead to a 6% increase in the human development index in the short run. Information and communication technology had a p-value of 0.17 and a negative coefficient, and it was not statistically significant at 10%. Life expectancy and unemployment were also not statistically significant in the short run period.

HETEROSCEDASTICITY AND SERIAL CORRELATION TEST

The Breusch-Pagan Test was used to test for heteroscedasticity in this research. Below are the results.

Table 10: Heteroscedasticity test

| Heteroscedasticity test | P-value |
|-------------------------|---------|
| Breusch-Pagan Test | 0.08 |

Source: Researcher's Construct (2022)

The results depicted the presence of homoscedasticity as the p-value of 0.08 was greater than 0.05. To test for serial correlation the Generalised least squares was used. The results proved that there was no autocorrelation in the research.

POST -ESTIMATION TEST

Normality Test

To test for normality, the Jarque-Bera test was used, and the results showed that the p-value of 0.682 was greater than the significance level of 5%. Therefore, the null hypothesis of having normal distribution was accepted. This implies that the data used was normally distributed.

5. CONCLUSION AND RECOMMENDATIONS

This study sought to examine the role of ICT in poverty reduction with a specific focus on the COMESA region. Based on the research findings it is clear that ICT is a useful tool that can be used for effective poverty reduction. Thus, the diffusion of ICT to productive sectors of the economy can be very effective in solving poverty through the multiplier effect. Use of ICT in productive sectors can create jobs, increase output, increase exports just to mention but a few. The following policy recommendations are suggested:

Promoting high usage of mobile phone usage

The COMESA region must improve and promote mobile phone usage. This can be accomplished by ensuring that all marginalized people who do not have access to mobile phones are provided with one. To achieve this, all member states' governments can devise effective policies that enable mobile phone manufacturers and suppliers to tap into the untapped market of people who do not have access to mobile phones. Another option is to incentivize or provide subsidies to such businesses so that the final price of mobile phones is affordable. This will enable the less fortunate to afford mobile phones and, in turn, to use them for economic activities, thereby raising the living standard

Promoting increased usage in internet usage

The governments of the COMESA region must encourage their citizens to use the internet. This can be accomplished by allowing more players into the telecommunications sector. More players will improve the sector's efficiency and, in turn, lower internet prices, *ceteris paribus*. Apart from that, the COMESA region must develop policies to promote internet usage, with a focus on affordability, particularly for COMESA's poorest communities. As a result, internet access will expose more COMESA citizens to economic and other commercial activities that can aid in the promotion of entrepreneurial activities. In a long-run this will aid to improve living standards as entrepreneurial activities can create job market expansion as well as improvement of living standards. Limited access to the internet implies that people will also have limited access to economic opportunities that can help to improve their living standards.

Creation Regional Research Hub

The COMESA trading bloc needs to set up a regional research hub. The research hub should be created with an aim of fostering research in diverse thematic areas that affect the region. Some of the areas are but are not limited to poverty, conflicts, ICT, and unemployment among others. Thus applied research will help as a tool for providing informed policies that tackle the problems faced by the region at large. The research hub will be useful in the cross-pollination of ideas and providing key panaceas to the most pressing issues in the COMESA region.

Implementing robust trade policies and trade agreements

The COMESA trading bloc must craft and implement robust trade policies. These policies should be tailor made to meet the member states trade needs. This will enable the flow of foreign currency within the COMESA region, create employment opportunities and allow for sharing of diverse human capital skills. However, caution should be taken to ensure that these policies are reviewed periodically since the macro environment is dynamic. Thus any significant changes in the micro-environment that affect trade should require policymakers to review existing trade policies. In the

long-run, robust and efficient trade policies will help in reducing poverty levels as more trading opportunities will benefit the member states.

Trade agreements should be designed by the COMESA region so that the trading block can trade with other trading parties such as the European Union, and ASEAN Economic Community just to mention but a few. This is essential, especially in harnessing some of the modern technology required by the COMESA region. Apart from that, this will also help in ensuring that all trading blocs gain from the exportation and importation of goods and services.

Improvement in ICT policies

ICT policies should be tailor made to ensure that both mobile telephone usage and internet usage are increased across the COMESA region populace at large. Thus, ICT should be prioritised at all levels and in different sectors of the economy. This can be in the small to medium enterprises sector, educational sector, government structures as well as the manufacturing sector. Apart from that, policies to be developed should ensure that digital illiteracy is eliminated so that all member states of COMESA can fully benefit from ICT usage.

VALIDATING A FASHION LEADERSHIP SCALE WITHIN THE SOUTH AFRICAN CONTEXT

M. van Deventer

North-West University, Vanderbijlpark, South Africa

ABSTRACT

Fashion leaders significantly contribute to an economy's clothing segment given the noteworthy role they play in influencing fashion followers to purchase fashion clothing. As such, it is key to comprehend the factors that influence fashion leadership. To this end, the purpose of this paper was to validate a fashion leadership scale within the South African context, which, based on a widespread search of online academic databases, lacks in South Africa. To validate fashion leadership as a six-factor structure, a total of 400 Generation Y male students completed a self-administered survey. A descriptive research design informed the methodology applied. Correlation analysis, multicollinearity and reliability measures, and confirmatory factor analysis using the maximum likelihood method made up the data analysis. The results obtained from the confirmatory factor analysis validated fashion leadership as a six-factor structure that consists of fashion leadership, product knowledge, decision-making confidence, fashion consciousness, mood enhancement and brand switching. The results also show that the measurement model exhibits internal consistency and composite reliability as well as the different types of validity, namely construct, convergent, discriminant and nomological validity. In addition, no signs of multicollinearity were evident between the factors of the measurement model. In terms of model fit, all fit indices, which included the IFI, TLI, CFI, SRMR and RMSEA returned values indicative of a good fitting model. This study concluded that this six-factor model is a reliable and valid instrument of fashion leadership and is the first validated fashion leadership scale within a South African context.

Keywords: Measurement model; confirmatory factor analysis; validation, fashion leadership; South Africa

1. INTRODUCTION

Marketing practitioners and researchers have been fascinated with fashion leadership and its ability to shape consumer behaviour (Goldsmith et al., 1991; Kang & Park-Poaps, 2010; Lang & Armstrong, 2018). This is because fashion retailers need to ensure that fashion innovations are diffused into the current market by positioning fashion items in a way that guarantees sales and increased profitability (Rahman et al., 2014). As such, product acceptance by fashion leaders is crucial, since fashion leaders are responsible for communicating fashion-related ideas to the next group of adopters, thereby assisting in new fashion clothing acceptance (Beaudoin et al., 2000; Kang & Park-Poaps, 2010; Lee & Workman, 2014; Lang & Armstrong, 2018), and also contributing to the economy.

Globally, the fashion industry has a market value of US\$ 3 trillion and accounts for two percent of global gross domestic product (GDP) (Fashion United, 2022). Major international consultancy agencies, such as McKinsey, Deloitte Group and the Boston Consulting Group, agree that today's

fashion retailers operate in an extremely competitive environment that is subject to unexpected changes and uncertainty (Gazzola et al., 2020). Technological advancements, which have a noteworthy impact on fast production methods and the consumption of fast fashion clothing items, are among some of the most dramatic changes witnessed by fashion retailers (Koksal, 2014). In addition, the fashion leadership tendencies of consumers are changing, effecting change in the fashion industry.

Fashion leadership is an internal characteristic that influences consumers' response to new fashion developments. Moreover, it is an essential concept to take into account in fashion consumption, since fashion leaders have a central role to play in the diffusion of fashion change (Goldsmith et al., 1993; Kim & Hong, 2011). In addition, fashion leaders are consumers who accelerate fashion change by being the very first people to shop for, acquire and consume the latest fashion clothing, subsequently convincing others to do the same. Furthermore, fashion leaders are concerned about their physical appearance and pay special attention to how others perceive them (Lee & Workman, 2014). As such, it is essential to note consumers' fashion leadership tendencies. To this end, a validated fashion leadership scale is required, which, based on a widespread search of online academic databases, lacks in South Africa. As such, this study's purpose was to validate fashion leadership as a six-factor structure that comprises fashion leadership, product knowledge, decision-making confidence, fashion consciousness, mood enhancement and brand switching.

2. LITERATURE REVIEW

Fashion may be viewed as a dual concept; firstly, fashion is continuously changing and is dynamic in nature, suggesting that fashion revolves around timeframes with changes in market tastes and needs, and secondly, the survival of fashion through time depends largely on society's acceptance of certain standards. Therefore, what is fashionable has a direct link to relevance, based on the consumers' attitude and perceptions at a specific time. Typically, the word fashion relates to clothing (Dlodlo, 2017). However, fashion can also refer to all the items that could possibly be placed on the body (Hourigan & Bougoure, 2012), such as bags, hats, shoes, sunglasses and clothes (Liu et al., 2021). Despite the wide scope of product items associated with this term, for this study's purpose, fashion relates to clothing. Clothing was specifically chosen as clothing is a dominant category of consumer products in South Africa's fashion industry with an expected revenue of US\$ 1.3 billion in 2025, compared to accessories and footwear with an expected revenue of US\$ 494 million and US\$ 102 million, respectively (Statista, 2022). In addition, the clothing segment is considered important for the global fashion industry (Castro & Ramirez, 2020).

Fashion is fundamentally changing the world and reshaping consumers' thinking (Naidu, 2018). As such, fashion retailers need to ensure that fashion innovations are diffused into the current market by positioning fashion products that guarantee improved profitability and sales (Rahman et al., 2014). Understanding fashion leadership behaviours will aid retailers and marketing practitioners to formulate valuable and successful marketing strategies and, ultimately, influence fashion leadership behaviour (Kang & Park-Poaps, 2010). In addition, it is essential to understand fashion leaders and their behaviours, because they influence non-fashion leaders to buy/use fashion clothing (Engelbrecht, 2016).

Fashion leadership is described as consumers who accept fashion trends early in the product lifecycle before the trend reaches the mass market (Goldsmith et al., 1993, as cited in Shephard et

al., 2016). Moreover, fashion leadership can be defined as “the adoption stage of fashion related items” (Goldsmith et al., 1993, as cited in Shephard et al., 2014:277). Fashion leadership represents the mass acceleration of the latest fashion trends, which include two major dimensions, namely fashion innovativeness and opinion leadership (Kang & Park-Poaps, 2010). Fashion innovativeness refers to “a personality trait towards adopting new fashion goods” (Park et al., 2007:204). “Opinion leadership is the idea that communication flows are segmented and that participants can be divided into different communicative roles, with some providing information or orientation and other following” (Schäfer & Taddicken, 2015:961). Collectively, the term fashion leadership can be explained as consumers who show an interest in fashion before other consumers, who are one of the first to purchase the latest fashions and who are more confident in their own taste. In addition, fashion leaders play an influential role on others to adopt and purchase the latest styles (Koksal, 2014).

Fashion leaders generally have a greater need for excitement and fun or enjoyment (Goldsmith et al., 1993); therefore, fashion leaders hold different value sets and psychological characteristics than average consumers do (Hahn et al., 2017). As indicated by the name, fashion leaders are typically the front-runners in searching for, purchasing and wearing the latest fashion before the fashion is accepted by other people (Dlodlo, 2017). Consequently, the “French label *avante garde* has been used to describe these individuals, meaning that fashion leaders are fashion forward” (Frings, 2005:54). Moreover, fashion leaders are confident in their fashion tastes because they depend heavily on the advice of fashion stylists regarding fashion trends (Dlodlo, 2017). Fashion leaders differ significantly from fashion followers in terms of personalities and information-seeking behaviour. This is because “fashion leaders are stimulated by achievement and need to express originality or uniqueness” (Frings, 2005:55). Fashion leaders are more inclined to acquire information through reading fashion magazines, going on a recreational shopping orientation, fashion shopping, purchasing the latest fashion items, being involved in fashion and impulsively purchasing products (Workman & Cho, 2012). In doing these activities, fashion leaders gain a wealth of information that they can convey to other people. Moreover, word-of-mouth communication is stimulated by individuals’ expressive behaviour and particularly by fashion leaders who, because of their high interest and involvement in fashion, are sensitive to the appearances of others. Fashion leaders not only provide information, but also reflect and communicate norms. Moreover, fashion leaders are characterised as individuals who have high fashion interest and high fashion involvement. As such, they participate in activities that provide abundant information (Lee & Workman, 2014). Taken together, fashion leaders are individuals who bring about fashion change as they are the first to purchase and wear the latest fashion clothing (i.e. fashion innovators), influence non-fashion leaders to purchase and wear the latest fashion clothing (i.e. fashion opinion leaders) or fulfil both roles (i.e. innovative communicators).

Fashion leaders, generally, are young (Quigley & Notarantonio, 2009), single and have higher education levels than other consumer groups (Viera, 2009). For this reason, this study used Generation Y students as the sample. Generation Y consumers, defined as “individuals born between 1986 and 2005” (Markert, 2004:21), are opinion leaders and trendsetters among their peers (Bevan-Dye & Akpojivi, 2016), egocentric and socially conscious (Coelho & Las Casas, 2013) and make up about 35 percent of South Africa’s population (Statistics South Africa, 2021), which render them an important market segment for any industry, including the fashion industry.

Generation Y consumers spend a large amount of their money purchasing clothes (Bakewell & Mitchell, 2003). Moreover, Generation Y supports fast fashion retailers such as H&M and Zara that offer sustainable clothing lines (Johansson et al., 2017), as these retailers adhere to this generation's personal, environmental and social value sets (Hwang & Griffiths 2017; Todeschini et al., 2017). Members who belong to this cohort perceive the activity of shopping for fashion products as consciously consuming, inevitably defining themselves and expressing their personality (Ordun, 2015). Consumers of this cohort find pleasure in shopping, value prestigious characteristics associated with purchased items and the quality of new, original and unusual fashion clothing (Williams & Page, 2011). As such, Generation Y members are extremely fashion and brand conscious clusters of consumers. Williams and Page (2011) indicate that Generation Y members are increasingly obsessed with fashion. Furthermore, Tee et al. (2013) assert that their spending patterns have positively impacted sales in the marketplace.

The lifestyle habits of the Generation Y cohort are different from those of the previous generations and their pace of life is relatively fast (Ladhari et al., 2019). For instance, their need for fashion can easily transition from daytime to evening wear. As such, it is no surprise that this cohort is the driving force behind current fashion trends (Gazzola et al., 2020). In terms of male fashion, Generation Y males have been socialised to perceive fashion in a more favourable light as opposed to generations of the past (Bakewell et al., 2006). The combined efforts of the media, commercial practice as well as the change in generational roles, have set up new cultural norms whereby Generation Y males tend to take more notice of fashion trends and are more likely than males of previous generations to be involved with fashion (Noh et al., 2015; Sung & Yan, 2020). As such, it is important that fashion retailers understand the factors that influence Generation Y consumers in general, and specifically Generation Y males' fashion leadership tendencies, as their fashion leadership could potentially have an influencing role on the purchasing behaviours of other consumer groups. To this end, a validated fashion leadership scale is necessary. Therefore, the purpose of the study is to answer the research question stated below:

Is fashion leadership among Generation Y male students a six-factor structure that consists of fashion leadership, product knowledge, decision-making confidence, fashion consciousness, mood enhancement and brand switching?

3. METHODOLOGY

3.1 Research design

Quantitative data was used to validate a fashion leadership scale; that is, a descriptive research design. In addition, a sample was selected from the interested population only once, making this a single cross-sectional study.

3.2 Sampling method

To select a sample of 500 Generation Y male students (18- to 24-year-old) registered at two HEIs in South Africa (250 per campus), a non-probability convenience sampling method was used. Judgement sampling was used to select the two HEIs from the 26 HEIs in South Africa.

3.3 Research instrument

Validated scales were used to develop a self-administered questionnaire. Each scale included three scale-response items, which were adapted from these validated scales. To measure fashion leadership, a scale validated by Goldsmith et al. (1993) was used, while product knowledge was measured using the scale developed by O’Cass (2004). Moreover, a scale validated by O’Cass (2000) was used to measure decision-making confidence, whereas fashion consciousness was measured using Nam et al.’s (2007) scale items. Mood enhancement was measured using the scale validated by Kwon (1992), and brand switching was measured using items from scales validated by Van Trijp et al. (1996) and Raju (1980). A Likert-type scale was used to measure the responses to the scaled items, and consisted of six points, namely strongly disagree, disagree, slightly disagree, slightly agree, agree and strongly agree.

Included as part of the questionnaire is a cover letter that explained the study in short as well as how the participant would be protected in terms of personal information. In addition, some demographic and fashion background information was requested.

3.4 Data collection

Before data collection commenced, ethics clearance was obtained from both HEIs to conduct the study. Thereafter, the study was discussed with participating university staff members at each HEI in order to finalise arrangements for dropping off the questionnaires. Two experienced fieldworkers assisted with the drop-off. The HEIs were notified that participants should willingly agree to partake in the study and that no participant will be forced to complete a questionnaire. In addition, it was explained to the HEIs that the data will only be used for statistical purposes, that all information enclosed in the questionnaire is guaranteed, and that no personal questions linking the participant to the specific questionnaire will be included. The same information was shared with those who participated in the study, in the form of a cover letter attached to the questionnaire.

3.5 Data analysis

Two statistical programs were used to analyse the obtained data, namely IBM SPSS and AMOS, Version 27. As part of the data analysis, various statistical methods were applied to the dataset, including descriptive statistics, measures of reliability and validity and correlation analysis. In addition, diagnostics were run to assess the multi-collinearity between the factors. Lastly, following the maximum likelihood approach, confirmatory factor analysis was run.

4. RESULTS AND DISCUSSION

4.1 Demographics and fashion background

This study produced a response rate of 80 percent, given that only 400 of the 500 questionnaires were eligible for analysis. Of the sample, the majority was aged 22 years, followed by 21-year-olds. The majority of the sample spoke Sesotho, followed by those who spoke Tshivenda. Participants who originate from Gauteng made up the largest share of the sample, whereas those who originally come from the Western Cape made up the smallest portion of the sample. Participants in their second year of study made up 35 percent of the sample, compared to only three percent who were on post-graduate level. The sample comprised more than half traditional

university students, compared to approximately 47 percent of the sample registered at a university of technology. In terms of fashion background information, more than half of the participants (52.5%) consider themselves fashion leaders, whereas 44.5 percent of the sample do not. The most preferred clothing brand purchased by the sample was Nike, followed by less purchased fashion brands, Uzzi and Adidas. The majority of the sample spends between R801 and R1 000 on fashion clothing, compared to those who spend in the range of R500 and R800 (29.8%) and R1 001 and R2 500 (21.8%). The data pertaining to the sample and the reported fashion background information is detailed in Table 1.

Table 1: Sample

| | % | | % | | % |
|-----------------------|------|-------------------------------|------|----------------------------|------|
| Age | | Language | | Province | |
| 18 | 3.3 | Afrikaans | 5.0 | Eastern Cape | 7.2 |
| 19 | 13.8 | English | 2.3 | Free State | 12.8 |
| 20 | 17.3 | isiNdebele | 2.5 | Gauteng | 27.5 |
| 21 | 20.8 | isiXhosa | 7.5 | KwaZulu-Natal | 5.0 |
| 22 | 21.5 | isiZulu | 14.2 | Limpopo | 25.8 |
| 23 | 15.0 | Sepedi | 5.8 | Mpumalanga | 6.5 |
| 24 | 8.5 | Sesotho | 21.0 | Northern Cape | 5.8 |
| Fashion leader | | Setswana | 9.5 | North West | 7.8 |
| Yes | 52.5 | SiSwati | 5.8 | Western Cape | 0.8 |
| No | 44.5 | Tshivenda | 14.8 | | |
| | | Xitsonga | 10.5 | | |
| Clothing brand | | Year of study | | HEI | |
| Adidas | 6.0 | 1 st -year student | 27.5 | Traditional | 53.5 |
| Daniel Hechter | 4.3 | 2 nd -year student | 35.0 | Technology | 46.5 |
| Identity | 5.5 | 3 rd -year student | 25.3 | Fashion expenditure | |
| Nike | 24.0 | 4 th -year student | 8.8 | R500-R800 | 29.8 |
| Rebat | 4.0 | Postgraduate student | 3.0 | R801-R1 000 | 48.5 |
| Relay Jeans | 3.8 | | | R1 001-R2 500 | 21.8 |
| Uzzi | 9.0 | | | | |
| Vans | 5.5 | | | | |

4.2 Descriptive statistics, reliability and validity and correlation analysis

To measure the degree of fashion leadership tendencies among Generation Y male students as well as their knowledge of and decision-making confidence in fashion clothing together with the extent of their fashion consciousness, them viewing fashion clothing as a mood enhancer and them engaging in brand switching behaviour, the mean (\bar{X}) and standard deviation (σ) were calculated for each factor. Owing to the Likert-type scale comprising six points, a higher mean value denotes greater agreement with the statements included in the factor being measured.

The validity and reliability of the scales were measured by calculating the mean inter-item correlation (MIIC) and Cronbach alpha (α) values, respectively. Clark and Watson (1995) recommend that the MIIC values should range between 0.15 and 0.50 for discriminant validity, whereas Cohen (1988) recommends a cut-off of 0.55. Zikmund and Babin (2013) suggest a Cronbach's alpha value of above 0.60 for internal-consistency reliability. In terms of the relationships between the factors and to evaluate the nomological validity of the proposed measurement theory, correlation analysis was done using Pearson's correlation. According to Malhotra (2010), nomological validity is evident when the relationship between each pair of factors is statistically significant. The output produced by SPSS concerning these statistics is outlined in Table 2.

Table 2: SPSS output

| Factor | \bar{X} | σ | MIIC | α | (1) | (2) | (3) | (4) | (5) |
|--------------------------------|-----------|----------|------|----------|-------|-------|-------|-------|-------|
| Fashion leadership (1) | 3.96 | 1.00 | 0.42 | 0.84 | | | | | |
| Product knowledge (2) | 3.94 | 1.03 | 0.48 | 0.79 | 0.74* | | | | |
| Decision-making confidence (3) | 4.63 | 1.00 | 0.57 | 0.80 | 0.43* | 0.47* | | | |
| Fashion consciousness (4) | 3.82 | 1.08 | 0.44 | 0.80 | 0.71* | 0.67* | 0.39* | | |
| Mood enhancement (5) | 4.21 | 1.00 | 0.40 | 0.73 | 0.60* | 0.58* | 0.34* | 0.60* | |
| Brand switching (6) | 4.21 | 1.04 | 0.38 | 0.72 | 0.58* | 0.45* | 0.35* | 0.52* | 0.51* |

Note: * Statistically significant at $p \leq 0.01$ (2-tailed)

The statistics in Table 2 reveal that all factors returned a mean value above 3.5, meaning that the participants view themselves as being fashion leaders, knowledgeable concerning fashion clothing as well as confident in making decisions regarding fashion clothing. Moreover, the participants' views suggest that they are fashion conscious, and that fashion clothing enhances their mood. Furthermore, evidence in the sample shows that the participants engage in brand switching behaviours.

The MIIC value for each factor exceeded 0.15, which suggests convergent validity of the items included in each scale. Although the MIIC value of the decision-making confidence scale slightly exceeded the 0.55 cut-off recommended by Cohen (1988), it is still reasonable to assert each of the scales' discriminant validity. Internal-consistency reliability of the scales is also evident, given the calculated Cronbach's alpha values for each factor above the cut-off of 0.60.

The relationships between each of the factors were statistically significant ($p \leq 0.01$), which implies the nomological validity of the measurement theory. The relationship between fashion leadership and product knowledge was the strongest ($r=0.74$, $p = 0.000 < 0.01$), whereas the weakest relationship was found between decision-making confidence and mood enhancement ($r = 0.34$, $p = 0.000 < 0.01$). Given that the strongest Pearson's correlation coefficient was below 0.90, the chances of multi-collinearity can be eliminated (Pallant, 2013). However, it is still advisable to test for more subtle forms of multi-collinearity.

4.3 Multi-collinearity diagnostics

Before confirmatory factor analysis was run, the independent factors were subject to a multi-collinearity check to assess more subtle forms of multi-collinearity. The dependent variable served as the subject number. For no serious multi-collinearity between the factors, Pallant (2010) recommends tolerance values above 0.10 and an average variance inflation factor lower than 10. The diagnostics for collinearity as calculated by SPSS are presented in Table 3.

Table 3: Diagnostics for collinearity

| Factor | Tolerance value | Variance inflation factor |
|----------------------------|-----------------|---------------------------|
| Product knowledge | 0.488 | 2.049 |
| Decision-making confidence | 0.829 | 1.207 |
| Fashion consciousness | 0.519 | 2.927 |
| Mood enhancement | 0.609 | 1.642 |
| Brand switching | 0.741 | 1.350 |

Constant = Dependent variable: Subject number

The diagnostics for collinearity, as presented in Table 2, indicate no serious multi-collinearity between the factors, with tolerance values between 0.519 and 0.829 and an average variance inflation factor of 1.835.

4.4 Measurement model

A six-factor measurement model was specified for confirmatory factor analysis using the maximum likelihood approach. This model consisted of fashion leadership, product knowledge, decision-making confidence, fashion consciousness, mood enhancement and brand switching, and each of these latent factors comprised three indicators. For model identification, each factor's first loading was fixed at 1. The notes for the model produced by AMOS indicate that there were 189 distinct sample moments and 69 distinct parameters to be estimated, producing 120 degrees of freedom (df) based on an over-identified model as well as chi-square (χ^2) of 328.687 ($p = 0.001$).

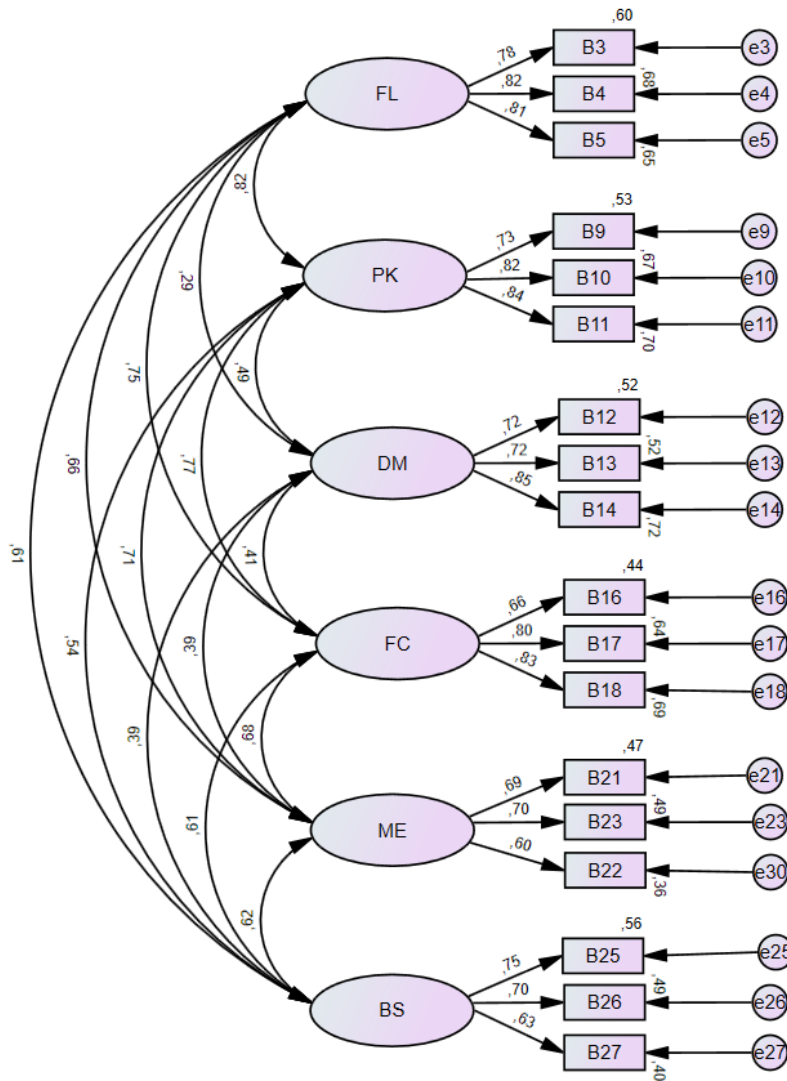

Hair et al. (2010) advise that a measurement model be assessed in terms of factor loadings exceeding 1 or that are below 1. In addition, it is important to assess the model in terms of negative error variances. These assessments were done to identify any potential problem estimates. The composite reliability (CR) and construct validity were determined by calculating the CR for each factor as well as the average variance extracted (AVE) and heterotrait-monotrait (HTMT) values. Malhotra (2010) suggests CR and AVE values above 0.70 and 0.50, respectively. However, Fornell and Larcker (1981) explain that an AVE value below 0.50 still suggests the convergent validity of the construct, if the composite reliability of the particular factor is above 0.60. For discriminant validity, Henseler et al. (2015) point out that the HTMT values should not exceed 0.85. Table 4 reports the estimates and the model reliability and validity, as well as the correlations for each factor and its observed variable.

Table 4: Confirmatory factor analysis.

| Latent factors | Standardised loading estimates | Error variance estimates | CR | AVE | HTMT | | | | |
|---------------------------------|--------------------------------|--------------------------|-------------|-------------|-------------|------|------|------|------|
| | | | | | F1 | F2 | F3 | F4 | F5 |
| Fashion leadership (F1) | 0.78 | 0.60 | 0.84 | 0.64 | | | | | |
| | 0.82 | 0.68 | | | | | | | |
| | 0.81 | 0.65 | | | | | | | |
| Product knowledge (F2) | 0.73 | 0.53 | 0.84 | 0.63 | 0.81 | | | | |
| | 0.82 | 0.67 | | | | | | | |
| | 0.84 | 0.70 | | | | | | | |
| Decision-making confidence (F3) | 0.72 | 0.52 | 0.81 | 0.58 | 0.30 | 0.52 | | | |
| | 0.72 | 0.52 | | | | | | | |
| | 0.85 | 0.72 | | | | | | | |
| Fashion consciousness (F4) | 0.66 | 0.44 | 0.81 | 0.59 | 0.77 | 0.81 | 0.41 | | |
| | 0.80 | 0.64 | | | | | | | |
| | 0.83 | 0.69 | | | | | | | |
| Mood enhancement (F5) | 0.69 | 0.47 | 0.70 | 0.44 | 0.65 | 0.70 | 0.43 | 0.69 | |
| | 0.70 | 0.49 | | | | | | | |
| | 0.60 | 0.36 | | | | | | | |
| | 0.75 | 0.56 | | | | | | | |
| Brand switching (F6) | 0.70 | 0.49 | 0.74 | 0.49 | 0.59 | 0.52 | 0.39 | 0.58 | 0.61 |
| | 0.63 | 0.40 | | | | | | | |
| | 0.75 | 0.56 | | | | | | | |
| | 0.70 | 0.49 | | | | | | | |
| Correlations | F1→F2: 0.82 | F1→F3: 0.29 | F1→F4: 0.75 | F1→F5: 0.66 | F1→F6: 0.61 | | | | |
| | F2→F3: 0.49 | F2→F4: 0.77 | F2→F5: 0.71 | F2→F6: 0.54 | F3→F4: 0.41 | | | | |
| | F3→F5: 0.39 | F3→F6: 0.39 | F4→F5: 0.68 | F4→F6: 0.61 | F5→F6: 0.62 | | | | |

The results in Table 4 show that there were no estimates above or below 1 as well as no negative error variances. In addition, the correlations in the table indicate a relationship ($p \leq 0.01$) between every latent factor and its observed variable. Each factor returned an acceptable CR value of 0.70 and above. While most factors calculated an AVE value of above 0.50, the factors of mood

enhancement and brand switching were slightly below at 0.44 and 0.49, respectively. However, because both of these factors' CR values were above 0.60, convergent validity is confirmed. Discriminant validity is also evident, given that none of the HTMT values exceeded 0.85. With convergent, discriminant as well as nomological validity confirmed, construct validity is verified. The measurement model is illustrated in Figure 1.

FL = Fashion leadership; PK = Product knowledge; DM = Decision-making confidence; FC = Fashion consciousness; ME = Mood enhancement; BS = Brand switching

Figure 1: Measurement model.

Having confirmed the measurement model's reliability and validity, model fit indices were calculated. The "incremental fit index (IFI), Tucker-Lewis index (TLI), comparative fit index (CFI), the standardised root mean residual (SRMR), the root mean square of approximation (RMSEA) and the chi-square statistic" (Van Deventer, 2018:191) were used to evaluate model fit. IFI, TLI and CFI values above 0.90 suggest acceptable model fit, whereas the computed RMSEA should equal 0.08 or less (Malhotra, 2010) and the SRMR 0.1 or less (Hair et al., 2010). Although a significant χ^2 was achieved, which suggests poor fit to the model (Byrne, 2010), the other model fit index values were indicative of acceptable model fit, with IFI equalling 0.94, TLI equalling 0.93, CFI equalling 0.94, SRMR equalling 0.047 and RMSEA equalling 0.063.

The measurement model results suggest that fashion leadership is a six-factor structure that demonstrates acceptable model fit, reliability as well as construct validity. Given the measurement model's validation, a structural model can be tested in accordance with theorised paths.

5. CONCLUSION

This study's purpose was to validate fashion leadership as a six-factor structure that consists of fashion leadership, product knowledge, decision-making confidence, fashion consciousness, mood enhancement and brand switching using a Generation Y male student sample. The latent factors exhibited internal-consistency reliability, CR and construct validity. In addition, the model fit indices used were indicative of a good model fit. Therefore, the study's results concluded that this six-factor structure is a valid and reliable measure of fashion leadership and is viewed as the first validated fashion leadership scale in South Africa. Insights gained from this study can assist fashion marketers and retailers to target their indented target market more effectively in their promotional efforts and gauge effective marketing strategies that will maximise sales and profits.

DIFFERENCES IN SOUTH AFRICAN GENERATION Y BANKING CONSUMERS' BANK IDENTIFICATION AND SELECTED BRAND PERSONALITY DIMENSIONS

M. van Deventer

North-West University, Vanderbijlpark, South Africa

ABSTRACT

Generation Y consumers, including banking consumers, generally display different levels of commitment and loyalty to a brand over the long run. As such, it is essential that retail banks create a brand that the Generation Y banking cohort can easily identify with. Retail banks that build a unique bank brand in terms of personality, particularly a brand personality that Generation Y consumers can relate to, will likely ensure loyalty towards the brand among this market segment, which is important for the retail bank's long-term success. Therefore, the purpose of this study was to determine whether there are differences in South African Generation Y banking consumers' bank identification and the brand personality dimensions of success, sophistication, sincerity, ruggedness, community driven and classic. A Generation Y banking consumer sample (N = 235) was conveniently selected from two Gauteng-based HEI campuses. A self-reporting questionnaire was used as a tool for collecting data and a descriptive research design was applied. To check for differences in the sample's bank identification and the selected brand personality dimensions, data analysis included an independent samples t-test as well as one-way analysis of variance (ANOVA). The results of the study suggest that males and females differ in their identification with their retail bank. In terms of brand personality, males and females associate the brand personality of community driven differently with their retail bank. However, no other differences were noted between males and females in terms of the personalities they associate with their retail bank. In addition, a difference was noted between bank identification and those participants who bank with Capitec and ABSA, while no differences were identified concerning the brand personality dimensions in this regard. Furthermore, consumers did not differ in their bank identification and brand personality in terms of the time period with their retail bank. Insights gained from this study could aid retail banks in better understanding the intended target market's degree of identification with the retail bank. In addition, retail banks can use the results of this study to determine whether the personality of the bank aligns with the characteristics of its consumers.

Keywords: Generation Y; banking; brand; bank identification; brand personality

1. INTRODUCTION

In South Africa, five retail banks mainly dominate the banking sector. These retail banks are Nedbank, Standard Bank, First National Bank (FNB), ABSA and Capitec (BusinssTech, 2019) and collectively, "they control nearly 90 percent of total banking sector assets" (Accenture, 2019). Although each of these retail banks offers financial services and products alike, they differ in terms of their distinct personality traits exhibited by the bank brand, otherwise known as brand personality, which Aaker (1997:347) describes as "a set of human characteristics associated with brands". Various authors agree that it is valuable to comprehend a brand's symbolic meanings

(Keller, 1993; Aaker, 1997; Carlson et al., 2009; Bang et al., 2014; Eren-Erdogmus et al., 2015), not only because brands play an influential role on the long-term sustainability of a business, but also because of its relationship building qualities with consumers (Tuškej et al., 2013). With insights gained from understanding a business's brand associations and meanings, a business can improve its performance financially. This increased financial performance stems from brand loyal consumers (Eren-Erdogmus et al., 2015), which holds many advantages for a business, such as lower marketing costs, favourable word-of-mouth, repeat purchases and a secured consumer base (Tsai, 2011). These brand loyalty benefits also hold true from a retail banking perspective. To take advantage of brand loyalty benefits, Koo and Kim (2013) suggest that businesses such as retail banks carefully consider displaying a brand personality that is not only robust, but also distinct. Furthermore, it is imperative that retail banks understand the factors that could influence their consumers' identification with the bank.

Within the context of retail banking, retail banks build brand personalities to set them apart from institutions that are similar in terms of their product and service offerings (Hopkins, 2017). According to Timerberlake (2013), retail banks might find it challenging to instil strong brand loyalty without having built a unique brand personality. A possible reason for this put forward by Moura (2021) as well as Wilson and Grant (2013) are that the personality of a brand connects and builds noteworthy associations, for example integrity and reliability, values and image with the bank. Therefore, Sung and Kim (2010) opine that a robust and healthy consumer-brand bond develops when there is alignment between the personality traits of the consumer and the bank brand. This alignment of personality traits, in turn, facilitates easier consumer identification with the bank, as explained by Carlson et al. (2009) and Moura (2021).

Identification with a brand, which, for the purpose of this study, is referred to as bank identification is described as consumers' "perceived oneness with the brand" (Stokburger-Sauer et al., 2013:6). From a brand management point of view, bank identification is essential, not only because consumers are increasingly sceptical about brands, but also because of the decreasing value in traditional media used to market brands (Tuškej et al., 2013). The literature concerning branding infers that there is an association between the personality of a brand and identification with a brand (Carlson et al., 2009). Taken from a retail bank's standpoint, this relationship means that if consumers can associate themselves with the personality of the bank brand, then the level with which they identify with the bank increases. As such, retail banks should not underestimate the value of understanding their consumers' degree of bank identification together with their perceptions about the brand personality of the bank, as this knowledge could give the retail bank direction in terms of their brand positioning, brand marketing and brand communication when targeting consumer cohorts in general, and specifically the Generation Y banking consumer cohort.

The Generation Y ["consumers born between 1986 and 2005" (Markert, 2004:21); also labelled the MTV Generation, youth, millennials and echo boomers (Rahman & Azhar, 2011)] banking segment is of particular importance to retail banks for a number of reasons. Firstly, these consumers represent nearly one third of the global population (Miller & Lu, 2018) and more than one third of South Africa's population (Statistics South Africa, 2021). As such, based on size, Generation Y is potentially a profitable consumer banking segment. The second reason why these consumers are important to retail banks can be explained in terms of the unique characteristics exhibited by these consumers. Generation Y influence the opinions of others (Werenowska &

Rzepka, 2020) and are in the forefront of setting trends (Friedmann, 2005; Doran, 2011; 3ManFactory, 2015). In addition, these egoistical, socially conscious (Coelho & Las Casas, 2013), technologically advanced and fickle (Osipow & Sheehan, 2014) consumers prefer to build strong relationships with brands that represent an image that is similar to the image they have of themselves and that is in line with their values (Lazarevic, 2012). Furthermore, Generation Y favour brands endorsed by celebrities and purchased by friends, influencers on social media and personalities in the media, and generally perceive brands as a token of prestige and a symbol of status (Osipow & Sheehan, 2014). The last reason why retail banks should focus on Generation Y as a consumer banking segment relates to their bank loyalty. It is difficult to predict Generation Y consumers' tendency to remain loyal to a brand (Lazarevic, 2012), given that these consumers' loyalty and commitment to one brand are generally short lived (Graywood, 2018). Grounded on these reasons, retail banks should differentiate their brand through creating a brand personality that enables easy identification with the bank among the indented target market such as Generation Y to untimely gain their long-term loyalty and commitment to the bank brand. As such, this study's purpose was to investigate whether Generation Y banking consumers differ in their identification with their bank and their perceived brand personality in terms of gender, banking institution and the time period with the bank.

2. LITERATURE REVIEW

Brands have been part of consumers' daily lives for years and are considered important for not only building consumer relationships, but also for the long-term sustainability of a business (Tuškej et al., 2013). As such, brand meanings and what they represent and symbolise captured the interest and attention of many scholars (Keller, 1993; Aaker, 1997; Carlson et al., 2009; Bang et al., 2014; Eren-Erdogmus et al., 2015). The personality of a brand is one of the symbolic meanings attached to a brand (Aaker, 1997). Consumers use the brand's personality to characterise themselves and articulate their self-perspective or self-identity (Aaker, 1997; Aaker & Biel, 2013; Ahmad & Thyagaraj, 2015; Srivastava & Sharma, 2016). From a practical perspective, the BMW automobile brand, for instance, is generally perceived by consumers as first-class, superior and elegant, whereas Jeep or Hummer is viewed as having opposite personalities such as tough, rugged and outdoorsy (Carlson et al., 2009). Therefore, the brand's personality shows the consumer the type of individual the brand is intending to be (Aaker & Biel, 2013).

In marketing, the most frequently applied brand personality scale is the one proposed by Jennifer Aaker (Moura, 2021). This scale is made up of five dimensions of personality, which include "ruggedness, sophistication, competence, excitement and sincerity" (Aaker, 1997:351, as cited in Eren-Erdogmus et al., 2015). Researchers from several countries have used this scale in many different markets. For example, in South Africa, a country with limited published brand personality studies, Sokhela (2015) applied Aaker's (1997) scale to high-end sedan car brands such as BMW, Mercedes-Benz and Audi, and found that Generation Y consumers associate the excitement, sophistication and competence personalities with these car brands. In his study, Shezi (2016) used the brand personality scale within a premier soccer league context and discovered that sophistication, ruggedness and sincerity are personalities that Generation Y students associate with their soccer team. Studies concerning the personalities of retail bank brands in South Africa could not be found. In terms of international studies, in the United States of America, this scale was applied within a restaurant context (Siguaw et al., 1999), apparel (Kim, 2000) and within a multiple

product category context (Monga & Lau-Gesk, 2007; Sung & Kim, 2010). In Australia, the brand personality scale was adopted and applied to the action sports clothing market (Buresti & Rosenberger, 2006), Formula 1 teams (Rosenberger & Donahay, 2008) and sponsors market (Donahay & Rosenberger, 2007) as well as the car market, in particular BMW and Volkswagen (Lau & Phau, 2007). Other international studies that applied this scale include Zentes et al. (2008) (country: Germany; application: retail brands), Balaji and Raghavan (2011) (country: India; application: corporate IT brands), Bouhleb et al. (2011) (country: North Africa; application: mobile phone brands) and Polyorat (2011) (country: Thailand; application: university brands).

Only three of Aaker's (1997) dimensions of brand personality were included in this study, namely ruggedness [tough and powerful brands (Mullan, 2020)], sincerity [brands that are truthful and down-to-earth (Mullan, 2020)] and sophistication [luxurious and superior brands (Eisend & Stokburger-Sauer, 2013)], together with three other personality traits, namely community driven [brands perceived to inspire and service consumers and their community (Braunstein & Ross, 2010)], classic [brands that are old school and old-style (Braunstein & Ross, 2010)] and successfulness [brand that are respected and effective (Braunstein & Ross, 2010)]. These specific brand personalities were tested given the uniqueness and dynamics of the banking industry in South Africa. In addition, after searching the internet and various academic databases, no brand personality study in a retail banking environment could be identified that included these six dimensions.

As mentioned in the introduction, it is key that retail banks create a profile of brand personalities with which their consumers can identify; that is, consumers' level of unity or belonging to the brand (Stokburger-Sauer et al., 2013). Brand identification (referred to as bank identification in this study) belongs to the theory of social identity (He et al., 2012) and takes place when the brand helps consumers to express their personalities, principles and views (Bhattacharya & Sen, 2003) and communicate their desires and status of oneself (Tuškej et al., 2013). For example, when a brand is successful or fails, consumers who have identified with the brand might also feel successful or feel like a failure. Therefore, brand identification represents the degree to which the identity of consumers is expressed and improved through the brand (Balaji et al., 2016). Literature suggests that the level of brand identification will determine consumers' level of pro-brand activity engagement such as how far they would be willing to go to protect the reputation of the brand, their level of support for the goals and products of the business, as well as their level of loyalty to the brand (He & Li, 2011). In addition, identification with a brand signifies a robust psychological connection with a brand, which can possibly last for a long period of time. Furthermore, consumers' identification with a brand is suggestive of their future behaviour (Rather, 2018). Taken from a retailing banking perspective, determining and having knowledge about brand identification are important for strong and long-lasting consumer-brand-relationships.

3. METHODOLOGY

3.1 Research design and sampling method

The research design that informed the methodology applied in this study was single cross-sectional and descriptive in nature. Two sampling methods were used to select the targeted population of 300 Generation Y banking consumers aged between 18 and 24 years at two of South Africa's

Gauteng-based higher education institution (HEI) campuses, namely non-probability convenience and judgement sampling. Convenience sampling was specifically chosen given time and cost constraints, and judgement sampling was employed to narrow down the 26 HEIs in South Africa to two campuses in Gauteng.

3.2 Research instrument

A questionnaire made up of two sections was developed for self-administration by the selected sample using validated scales. Accompanying the questionnaire was a cover letter. This cover letter explained the study and indicated that all information requested from the sample would be treated with utmost confidentiality and that the information provided will only be used for statistical analysis.

Section 1 of the questionnaire asked some demographics of the sample, as well as questions relating to their banking institution and the time period, they have been consumers of their bank. The questionnaire's second section included adapted scale items harvested from two validated studies. The first scale related to brand identification (Swanson et al., 2003) and was used to determine the extent to which the sample identifies with their chosen retail bank. The second scale used entailed selected brand personality dimensions (Braunstein & Ross, 2010) to determine the sample's perceptions about their chosen retail bank brand's personality. A Likert-type scale of measurement was used to scale the responses obtained from the sample. This scale comprised six rating points to measure the sample's agreement or disagreement with the statements included in the questionnaire [(1 = strongly disagree to (6) = strongly agree)].

3.3 Data collection

All ethical procedures, such as following the process for obtaining ethics clearance from both HEI campuses, were adhered to before collection of the data commenced. With ethics clearance obtained and the participating HEIs made aware of the study, what it entails and how data will be collected, fieldworkers were deployed to each campus to ask for voluntary questionnaire completion by the sampled participants. The mall-intercept survey method was used in this regard. The fieldworkers were asked to inform the sampled participants of the questionnaire's cover letter, which included important details pertaining to the anonymity of the provided information, purpose of the study as well as contact details of the researcher.

3.4 Data analysis

Version 27 of the IBM SPSS statistical program was employed to encapsulate and scrutinise the data collected from the sample. Several analysis tests were run in this program, including a one-sample t-test, an independent-sample t-test, correlation analysis, multi-collinearity analysis, one-way analysis of variance (ANOVA) as well as tests to obtain descriptive statistics of the captured data.

4. RESULTS AND DISCUSSION

4.1 Response rate, sample description and sample's banking background

Once the fieldwork was completed, the process of data cleaning commenced to ensure that only questionnaires completed by the specified target population were analysed. Only 235 of the 300 questionnaires could be analysed, giving this study a 78 percent response rate.

The sample was described in terms of the demographic data obtained. The sampled participants' ages ranged from 19 years of age to 24 years of age, which is in line with the defined population targeted. Moreover, the sample included somewhat more females than males. Furthermore, the Gauteng Province was identified as the province from which the majority of the sample originate, whereas the Northern Cape was represented the least in terms of the sample's province of origin. Lastly, the language most spoken by the sample was identified as isiXhosa, followed by Sesotho.

Concerning the sample's banking background information, most of the participants indicated Capitec as their banking institution, while Nedbank was identified as the least represented institution of banking by the sample. The duration the sampled participants have been with their chosen retail bank varied, with more than half of the sample indicating a time period of between one and three years with their retail bank, about 25% indicating less than one year and nearly 23% indicating that they have been banking with their retail bank for more than three years. The demographic and banking background data is tabled in Table 1.

Table 1: Demographics and banking background information.

| | % | | % |
|-----------------|------|----------------------------|------|
| Age | | Banking institution | |
| 20 | 21.7 | Capitec | 45.5 |
| 19 | 19.6 | ABSA | 19.6 |
| 21 | 18.7 | FNB | 15.3 |
| 18 | 15.7 | Standard Bank | 11.1 |
| 22 | 11.5 | Nedbank | 8.5 |
| 23 | 10.6 | Language | |
| 24 | 2.1 | isiXhosa | 23.8 |
| Gender | | Sesotho | 17.4 |
| Female | 50.6 | Afrikaans | 15.3 |
| Male | 49.4 | isiZulu | 10.6 |
| Province | | Sepedi | 7.7 |
| Gauteng | 40.9 | Xitsonga | 7.7 |
| Eastern Cape | 20.9 | Setswana | 7.2 |
| Limpopo | 16.2 | Tshivenda | 5.5 |
| Free State | 7.7 | SiSwati | 3.0 |
| Mpumalanga | 6.0 | English | 1.7 |
| North West | 4.3 | Duration with bank | |
| KwaZulu-Natal | 3.8 | 1-3 years | 52.3 |
| Northern Cape | 0.4 | Less than a year | 25.1 |
| | | More than 3 years | 22.6 |

4.2 Descriptive statistics, reliability and validity and correlation analysis

To measure the extent to which Generation Y banking consumers associate with their banking institution and consider their retail bank as successful, sophisticated, sincere, rugged, community driven and classical, a mean (\bar{X}) value and standard deviation (σ) were calculated for each construct. As previously mentioned, the Likert-type scale used consisted of six rating points, which

means that the higher the value of the mean, the greater agreement participants have with the statements included in the construct.

Two statistical measures were employed to test the internal-consistency reliability and discriminant and convergent validity of the scales, namely the Cronbach’s alpha (α) and the mean inter-item correlation coefficient (MIIC), respectively. For internal-consistency reliability, the “Cronbach alpha should exceed 0.60” (Zikmund & Babin, 2013). “For convergent and discriminant validity of the scale”, the MIICs should “range between 0.15 and 0.50” (Clark & Watson, 1995). These results, together with the descriptive statistics and the one-sample t-test results are presented in Table 2.

Table 2: Analysis test results.

| Construct | \bar{X} | σ | α | MIIC | t-values | p-values |
|---------------------|-----------|----------|----------|-------|----------|----------|
| Bank identification | 3.838 | 1.18 | 0.768 | 0.397 | 49.99 | 0.001* |
| Success | 4.975 | 0.66 | 0.910 | 0.430 | 115.89 | 0.001* |
| Sophistication | 4.899 | 0.69 | 0.849 | 0.415 | 108.48 | 0.001* |
| Sincerity | 4.911 | 0.73 | 0.801 | 0.449 | 102.97 | 0.001* |
| Rugged | 4.574 | 0.88 | 0.662 | 0.422 | 80.12 | 0.001* |
| Community driven | 4.701 | 0.86 | 0.640 | 0.381 | 83.52 | 0.001* |
| Classical | 3.647 | 1.01 | 0.600 | 0.291 | 55.26 | 0.001* |

*Significant at $p \leq 0.05$ (2-tailed)

The mean values highlighted in Table 2 were all above 3.5, which indicates that the participants agree with the statements included in the scale. More specifically, the Generation Y banking consumers associate themselves with their retail bank and view their bank brand as displaying personality traits such as great performance and efficiency (successfulness), trendy and innovative (sophistication), kind, authentic and honest (sincerity), daring and bold (ruggedness), inspiration and service orientation (community driven) as well as conservative and old-school (classical). In addition, the p-values derived from the one-sample t-test suggest that these means were all statistically significant ($p \leq 0.05$).

The lowest Cronbach’s alpha was recorded for the brand personality of community driven ($\alpha = 0.60$), while the highest α was recorded for successfulness at 0.91, thereby confirming the internal consistency of the scales used. In terms of validity, the MIICs were between 0.15 and 0.50, thereby warranting the scales’ convergent and discriminant validity.

To report on the relationships and multi-collinearity between the constructs, a Pearson’s product-moment correlation coefficient matrix was developed and the diagnostics for collinearity test was run, respectively. Table 3 reports on the results.

Table 3: Pearson’s product-moment correlation and multi-collinearity.

| Construct | Correlation matrix | | | | | | Collinearity diagnostics | |
|-------------------------|--------------------|--------|--------|--------|--------|--------|--------------------------|-------|
| | 1 | 2 | 3 | 4 | 5 | 6 | TV | VIF |
| Bank identification (1) | 1 | | | | | | 0.420 | 2.380 |
| Successfulness (2) | 0.247* | 1 | | | | | 0.453 | 2.209 |
| Sophistication (3) | 0.205* | 0.624* | 1 | | | | 0.376 | 2.658 |
| Sincerity (4) | 0.220* | 0.690* | 0.691* | 1 | | | 0.639 | 1.566 |
| Ruggedness (5) | 0.156** | 0.472* | 0.511* | 0.538* | 1 | | 0.444 | 2.250 |
| Community driven (6) | 0.323* | 0.656* | 0.567* | 0.623* | 0.483* | 1 | 0.761 | 1.313 |
| Classic (7) | 0.133** | 0.315* | 0.246* | 0.346* | 0.330* | 0.463* | 0.453 | 2.209 |

* Significant at $p \leq 0.01$

** Significant at $p \leq 0.05$

The correlation matrix in Table 3 shows that there were statistically significant ($p \leq 0.01$; $p \leq 0.05$) relationships between each construct pair, inferring nomological validity (Malhotra, 2010). Interestingly, the two brand personalities that have the sturdiest relationship with bank identification among the Generation Y consumer banking sample were community driven ($r = 0.323$) and successfulness ($r = 0.247$). Although the highest correlation coefficient of 0.691 was below 0.90, which, according to Pallant (2013) eliminates the chances of multi-collinearity, the collinearity statistics were still computed to assess more subtle forms of multi-collinearity.

Tolerance values (TV) that are greater than 0.10 and an average variance inflation factor lower than 10 suggest no serious multi-collinearity (Pallant, 2010). The collinearity statistics in Table 3 suggest no serious multi-collinearity between the constructs, with the lowest TV of 0.376 being well above 0.10 and the VIF of 2.08 being well below 10.

4.3 Independent samples t-test

To evaluate whether Generation Y banking female and male consumers differed in their bank identification and perceived brand personality, an independent samples t-test was run. This test pointed out two differences that were statistically significant ($p \leq 0.05$) among females and males, one in terms of bank identification and one concerning the brand personality of community driven. Generation Y female banking consumers have a higher degree of identification with their retail bank compared to Generation Y male banking consumers. In addition, female banking consumers associate the brand personality of community driven more with their retail bank compared to their male counterpart. The results of the analysis are captured in Table 4.

Table 4: Differences in Generation Y banking female and male consumers' bank identification and perceived brand personality.

| Construct | Male (n=116) | | Female (n=119) | | t-value | p-value |
|---------------------|--------------|----------|----------------|----------|---------|---------|
| | \bar{X} | σ | \bar{X} | σ | | |
| Bank identification | 3.50 | 1.174 | 4.16 | 1.089 | -4.474 | 0.000* |
| Success | 4.92 | 0.680 | 5.03 | 0.633 | -1.361 | 0.175 |
| Sophistication | 4.83 | 0.727 | 4.97 | 0.653 | -1.491 | 0.137 |
| Sincerity | 4.84 | 0.823 | 4.97 | 0.625 | -1.360 | 0.175 |
| Rugged | 4.55 | 0.898 | 4.60 | 0.855 | -0.442 | 0.659 |
| Community driven | 4.55 | 0.958 | 4.85 | 0.731 | -2.743 | 0.007* |
| Classic | 3.59 | 1.110 | 3.70 | 0.907 | -0.861 | 0.390 |

*Statistically significant at the 0.05 level

4.4 ANOVA

One-way ANOVA was used to check whether Generation Y consumers who bank with different retail banks differ in their bank identification and perceived brand personality. These differences are indicated in Table 5.

Table 5: Differences in bank identification and perceived brand personality among Generation Y consumers who bank with different retail banks.

| Construct | | ANOVA | | | | |
|---------------------|----------------|----------------|-----|-------------|-------|---------|
| | | Sum of squares | df | Mean square | F | p-value |
| Bank identification | Between groups | 12.901 | 4 | 3.225 | 2.384 | 0.052* |
| | Within groups | 311.195 | 230 | 1.353 | | |
| | Total | 324.095 | 234 | | | |

| ANOVA | | | | | | |
|------------------|----------------|----------------|-----|-------------|-------|---------|
| Construct | | Sum of squares | df | Mean square | F | p-value |
| Successfulness | Between groups | 2.212 | 4 | 0.553 | 1.283 | 0.277 |
| | Within groups | 99.113 | 230 | 0.431 | | |
| | Total | 101.325 | 234 | | | |
| Sophistication | Between groups | 1.237 | 4 | 0.309 | 0.641 | 0.634 |
| | Within groups | 110.894 | 230 | 0.482 | | |
| | Total | 112.131 | 234 | | | |
| Sincerity | Between groups | 1.658 | 4 | 0.414 | 0.773 | 0.544 |
| | Within groups | 123.386 | 230 | 0.536 | | |
| | Total | 125.043 | 234 | | | |
| Ruggedness | Between groups | 0.649 | 4 | 0.162 | 0.209 | 0.933 |
| | Within groups | 178.576 | 230 | 0.776 | | |
| | Total | 179.225 | 234 | | | |
| Community driven | Between groups | 0.837 | 4 | 0.209 | 0.278 | 0.892 |
| | Within groups | 173.335 | 230 | 0.754 | | |
| | Total | 174.172 | 234 | | | |
| Classical | Between groups | 7.399 | 4 | 1.850 | 1.833 | 0.123 |
| | Within groups | 232.063 | 230 | 1.009 | | |
| | Total | 239.463 | 234 | | | |

Note: * Statistically significant at $p \leq 0.05$ (2-tailed)

As indicated in Table 5, there were no statistically significant differences between ABSA, Capitec, FNB, Nedbank and Standard Bank Generation Y consumers and the various brand personalities. However, a statistically significant difference ($p \leq 0.05$) was found between Generation Y consumers of the different retail banks and bank identification. As revealed by the Tukey HSD test, Capitec consumers exhibited a higher degree of bank identification ($\bar{X} = 4.07, \sigma = 1.24$) than ABSA consumers did ($\bar{X} = 3.47, \sigma = 1.16$).

ANOVA was also used to check whether Generation Y consumers differed in their bank identification and brand personality when taking the time with the retail bank into consideration. Interestingly, as indicated in Table 6, no statistically significant differences were found between Generation Y banking consumers' bank identification and brand personality and the time period with the retail bank.

Table 6: Differences in bank identification and perceived brand personality among Generation Y consumers in terms of the time period with their bank.

| ANOVA | | | | | | |

Note: * Statistically significant at $p \leq 0.05$ (2-tailed)

5. LIMITATIONS AND FUTURE RESEARCH

The objective assessment of this study's findings was limited given the non-probability convenience sampling method used. Moreover, this study was limited to two university campuses in one particular region of South Africa. As such, the opportunity exists to duplicate this study on a larger scale by including more Generation Y consumers across several university campuses situated in various provinces of South Africa. In addition, longitudinal and comparative studies could be considered for future research.

6. CONCLUSION

Generation Y banking consumers' loyalty to brands, including their loyalty to retail bank brands, consistently fluctuates. To ensure improved levels of loyalty among this segment of consumers, retail banks are encouraged to continually evaluate their brand in terms of brand identification and personality to ensure that the intended target market can easily identify with the brand as well as associate with the brand's personality traits. As such, the aim of this study was to determine whether Generation Y banking consumers differed in their bank identification and perceived brand personalities in terms of gender, banking institution and time period with bank. This study concluded that Generation Y female and male banking consumers differ in their identification with their bank. More specifically, female consumers more easily identify with their retail bank than male consumers do. In addition, females associate the brand personality of community driven with their retail banks to a higher extent compared to males. Although this study concluded that the period that Generation Y consumer's bank with their retail bank played no role in their bank identification and perceived brand personality, this study found that Capitec consumers more easily associate themselves with their bank compared to ABSA consumers. Given these conclusions, retail banks are advised to use the results of this study to better understand the Generation Y banking segment's bank identification and perceived brand personality to ensure greater identification with the bank and improved acceptance of the brand to ensure increased brand loyalty.

INTERPRETIVE STUDY OF COMMERCIALISATION OF MEDICINAL PLANTS IN SOUTH AFRICA: PROSPECTS AND CHALLENGES

N.F. Shibambu

University of Limpopo, Sovenga, South Africa

ABSTRACT

The aim of this study was to analyse the commercialisation of medicinal plants in South Africa, in order to identify existing commercialisation prospects and challenges. Notably, these plants can be used for primary health care and food, amongst others. This rationale stemmed from the associated effects imposed by unregulated local traders (*Muthi* shop owners, street vendors and suppliers) selling medicinal plants. As a result, the depletion of these plants is negatively witnessed due to this commercialisation. From a qualitative standpoint, this study adopted the interpretive research design to support to employed systematic review method. Seminal studies on this subject were purposively collected using keywords extracted from the research topic. Only sources of high academic standing, with integrated ideas, and not separate writings on this topic were reviewed. To offer relevance and trustworthiness to the current study, the researcher confined his literature review to recent studies that were not older than 10 years. However, other studies that fell outside this period, but could provide greater significance to the topic, were considered. The collected data was analysed using the inductive Textual Content Analysis (TCA) method.

The results of this study reveal that commercialisation of medicinal plants drastically affect their availability, as some of the local traders seem to lack adequate conservation methods to minimise their depletion. The majority of the reviewed literature indicates that conservation methods are not correctly incorrectly applied and largely ignored in some instances owing to high demands of medicinal plants. This high demand often leads to harvesters to neglecting the correct conservation methods and procedures as they hurry to collect them for the market. It is concluded that the demand for medicinal plants for trade markets poses a threat to their availability in the future. Therefore, local traders need to take the necessary precautionary measures while harvesting them. Equally, the concerned parties should be consistently exposed to the improved resources, advanced training and better education about the benefits and importance of these plants.

Keywords: Commercialisation, Interpretative study, Medicinal plants, Prospects (and challenges), South Africa

1. INTRODUCTION

The World Health Organisation (WHO) (Olsen, 1998) estimates that 70-80 percent of the population around the world use medicinal plants. In various developing countries, including South Africa, medicinal plants perform a significant role for primary health care purposes (Fullas, 2007). The large population of which are rural people, depend largely on the natural resources that are found near them for the purposes of fuel wood and for medicine (Kasagana & Karumuri, 2011). Mander *et al.* (2007) states that the African Health Care System of South Africa has always been dependent of medicinal plants. This led to many people seeing an opportunity to commercialise medicinal plants and to generate income (Moeng, 2010; Van Wyk, 2013). The majority of South

African rural communities still prefer the use of indigenous medicinal plants to meet their primary health care needs, in spite of the availability and accessibility of western medical care services provided by the government (Williams *et al.*, 2013). De Wet *et al.* (2013) concur that even though some of the South African population have access to western health care services, they still prefer the use of medicinal plants as the primary health care to cure various diseases. In South African history, medicinal plants were the only primary source of medicines (Van Wyk & Prinsloo, 2018). Most people who use traditional medicines prefer them because of they are affordable, easily accessible and culturally acceptable (Maroyi, 2013).

In South Africa various factors play an essential role in the development of the country's economy and in the fight against unemployment. Although the selling of medicinal plants plays an important role in the development of the country's economy, it is also a contributing factor of exploitation of the natural resources that are found in the floral kingdom (Street & Prinsloo, 2013). As the human population grows, the demand for medicinal plants also increases, leading to an imbalance between supply and demand. Thus, commercialisation of medicinal plants becomes the challenge to the effective management of the way in which people harvest these plants and the number of plants they can harvest (Godoy & Bawa 1993; Dovie *et al.* 2002; and Luoga *et al.* 2004). Overexploitation of medicinal plants through indiscriminate harvesting and because of high demand (Street & Prinsloo, 2013), as well as their destruction through uncontrolled deforestation (Chen *et al.* 2016), poses a danger to their existence.

The International Union for Conservation of Nature (IUCN) Red List assessments was completed in South Africa in 2009 and identified 20 456 indigenous vascular plant taxonomies (Williams *et al.* 2013). During the process of the IUCN Red List assessments, medicinal plants that are sold in 'Muthi' shops and by street vendors were identified to be at high risk of extinction due to overexploitation (Williams *et al.* 2013). The commercialisation of South African medicinal plants remains low, because of inadequacy of existing laws to conserve and promote them (Ndhlovu *et al.* 2021). The promotion of the cultivation of these medicinal plants can encourage the economy by providing employment to the underprivileged (Ndhlovu *et al.* 2021).

Commercialisation of indigenous plant species and related harvests in South Africa is predictable to generate at least 134 000 income opportunities, since it is also estimated that approximately 72 percent of the black South African population, including those that are living in urban areas, still prefers the use of medicinal plant for the purposes of their primary health care (Williams *et al.* 2013). In South Africa the trading of medicinal plants, particularly in the summer-rainfall regions, are done on a large scale (Williams *et al.* 2013).

2. LITERATURE REVIEW

2.1 Demand of medicinal plants

The demand for medicinal plants has been rising, resulting in increased pressure on wild plant populations. This, and the lessening of habitats in several parts of the country, means that South African indigenous plants are now facing extinction (Grunwald & Buttel, 1996). As people migrate from rural areas to urban cities, they start to have limited access to indigenous plants because of the distance. Therefore, they rely on street vendors and 'Muthi' shop to supply them with medicinal plants for their primary health purposes. As urbanisation increases, so is does the demand for

medicinal plants (Williams *et al.* 2013). People in rural and urban areas have high demand for medicinal plants as they still perceive it as the main ingredient in traditional medical system and an important source of human survival and well-being (Ndhlovu *et al.* 2021). Despite the fact that most of South African rural areas have access to mobile clinics and other medical facilities, the service delivered seems to be insufficient in order for it to accommodate everyone (Moeng, 2010). Moreover, individuals believe that indigenous medicine is still effective, and do not trust anything that is Western and non-African (Moeng, 2010).

In South Africa the traditional health care system is dependent on medicinal plants (Moeng, 2010). Approximately 20 000 tonnes of indigenous plant materials, in a period of around a year, are used by South Africans (Moeng & Potgieter, 2010). There is a large quantity of these indigenous plants that are being commercialised mostly in informal ‘Muthi’ shops and ‘Muthi’ markets, and are usually harvested (Moeng & Potgieter, 2010). Medicinal plants are gathered from an extensive variety of habitats throughout the country. These habitats are usually found on communal lands, farms and protected areas (Moeng & Potgieter, 2010). South Africa has the authority to assess the status of the conservation of their indigenous plant species by using the standard IUCN Red List Categories, because of their high demands from ‘Muthi’ marketplaces (Williams *et al.* 2013). Moreover, South Africa became the only country that has evaluated the conservation significances of its whole flora in the whole world, using the IUCN Red List guiding principles but with additional three categories, namely, Critically Rare, Rare and Declining (Williams *et al.* 2013).

2.2 Commercialisation of medicinal plants

According to Cunningham (1991), the commercialisation of medicinal plants contributes to the multimillion-rand ‘hidden economy’ in South Africa. The trade of indigenous plants is currently higher than it was in the past because of the indigenous values associated with medicinal plants, the high human population growth and rapid urbanisation (Wiersum *et al.* 2006). The challenge of trading in medicinal plants at local level and their exploitation has been documented in various parts of the country over the years (Moyo *et al.* 2015). As the demand for medicinal plants increase, so does their commercial demand, this also contributes to their destructions, based on gathering practices, as well as rising of hereditary exposures to natural disasters, further resulting in serious threats on availability and supply of medicinal plants (Street & Prinsloo, 2013). One valuable source of income in many South African households in different provinces comes is trading of medicinal plants (Rasethe *et al.* 2019). This implies that the sales of medicinal plants in South Africa contribute both directly or indirectly to the economy of rural households through providing welfare and economic status (Ndlhovu *et al.* 2021). Some traditional health practitioners and indigenous knowledge-holders have taken an advantage to commercialise medicinal plants outside of traditional settings (Ndlhovu *et al.* 2021).

Table 1: Ten (10) most commonly commercialised medicinal plants in order of frequency

| No | Name | Frequency of Citation | Part used | Use value | Conservation status | Scarce in Market |
|----|-----------------------|-----------------------|--------------|-----------|---------------------|------------------|
| 1 | <i>Fabaceae</i> | 0.07 | Roots | 0.07 | Least Concern | Yes |
| 2 | <i>Asphodelaceae</i> | 0.40 | Leaves | 0.27 | Endangered | No |
| 3 | <i>Orchidaceae</i> | 0.20 | Stem, leaves | 0.13 | Least Concern | Yes |
| 4 | <i>Phyllanthaceae</i> | 0.13 | Roots | 0.13 | Not threatened | Yes |
| 5 | <i>Euphorbiaceae</i> | 0.07 | Roots | 0.07 | Vulnerable | No |
| 6 | <i>Combretaceae</i> | 0.20 | Roots | 0.33 | Protected | Yes |

| No | Name | Frequency of Citation | Part used | Use value | Conservation status | Scarce in Market |
|----|---------------------|-----------------------|-----------|-----------|---------------------|------------------|
| 7 | <i>Linaceae</i> | 0.13 | Roots | 0.13 | Protected | Yes |
| 8 | <i>Bignoniaceae</i> | 0.07 | Fruits | 0.07 | Not threatened | Yes |
| 9 | <i>Loganiaceae</i> | 0.07 | Roots | 0.07 | Not threatened | No |
| 10 | <i>Moringaceae</i> | 0.40 | Leaves | 0.33 | Protected | No |

Source: Barbosa, Hlashwayo, Sevastyanov, Chichava, Mataveia, Boane and Cala (2020).

Drawing from Table 1, Moeng (2010) shares that when gatherers are harvesting medicinal plants, most plants, such as *Fabaceae*, *Phyllanthaceae*, *Euphorbiaceae*, *Combretaceae*, *Linaceae* were and *Loganiaceae* are dug up and the whole plant is removed for medical practices. This practice puts the survival of these plants in danger with a possibility of extinction. On the other hand, with plants such as *Asphodelaceae*, *Orchidaceae* and *Moringaceae* only a certain number of leaves are removed, which gives them a chance to grow again for future use. In plants such as *Sclerochiton ilicifolius*, several numbers of roots are removed during collection; whereas with trees such as *Orchidaceae* only the bark is stripped for medical use (Moeng, 2010). The traditional medicine industry is unregulated. It has an estimated contribution 2.9 billion South African Rands (ZAR) and (USD) (192,948,107 Dollars to the economy per annum (Ndlhovu *et al.* 2021). As a result, many rural communities resort to the use of traditional medicine as an alternative medicine, a trend that has been observed in urban areas where there are many 'Muthi' markets (Ndlhovu *et al.* 2021).

2.3 Conservation methods of medicinal plants

The essential part of plants survival is influenced by human existence; this was recognised through the starting point of the ecosystem up to its conservation (Van Wyka & Prinsloo, 2018). Plants conservation is aimed at supporting the sustainable development of natural resources that are implemented in order to preserve and protect these medicinal plants through employing in methods that do not put danger in the existence and availability of medicinal plants or methods that do not destroy the important habitants and ecosystem up until where they come into extinct (Kasagana & Karumuri, 2011). Gatherers of medicinal plants utilise different methods of harvesting of which some threaten the existence of these plants. Some of these methods are safe for the survival of medicinal plants. They include removing parts of the bulk, collection of roots, bulb, uprooting the whole plant, and cutting stems and leaves (Rasethe *et al.* 2019).

These harvesting methods are used by plant gatherers, who often collects large quantities of medicinal plants, their actions remain a negative conservation concern. In some cases, the plant collectors use collection methods that are illegal in protected areas which also place the ecosystems in danger (Rasethe *et al.* 2019). The targeted population of medicinal plants is rapidly declining, and most of them are facing extinction without their therapeutic potential being fulfilled (Rasethe *et al.* 2019). Conservation methods, which are used to protect the plants' genetic resources has been previously realised as a fundamental factor for biodiversity conservation. Moreover, the 'In-Situ & Ex-Situ' conservation are the two main methods for conservation of indigenous plant species (Kasagana & Karumuri, 2011). According to Kasagana and Karumuri (2011), in South Africa law enforcement approach was used for conservation of medicinal plants, however, the approach has evidently been unsuccessful. New, effective and participatory methods are needed to protect medicinal plants.

To answer to the overexploitation and threat of natural resources such as medicinal plants, numerous efforts have been implemented in attempt to conserve the multiplicity of medicinal plants. Moeng and Potgieter (2011) highlight that Community-Based Natural Resources Management (CBNRM) are responsible for the conservation of medicinal plants. According to Moeng (2010), “*Muthi*” shop owners and street vendors play important role on the trade of South African indigenous plant species, and it is important for them to develop strategies to prevent loss of these plants. The indigenous plants die and eventually become extinct when the bark, roots or the entire parts of the plant are harvested. However, the gathering of leaves, flowers, fruits and seeds are considered less damaging to the plants, although, severe pruning affects a plant's dynamism and reproductive potential and their future existence (Van Wyka & Prinsloo, 2018). The sustainable rate of harvesting is determined by category of vegetation that is being collected, from which kind of the plants or parts of the plants that are collected, their richness and growth rates (Van Wyka & Prinsloo, 2018).

3. METHODOLOGY

From a qualitative standpoint, this study adopted the interpretive research design to offer support to employed systematic review method. Dan (2017) states that this research design is meant to evaluate the improvement in a specific study field. Moreover, the aim of this research design is to recognise, assess and summarise the outcomes of the reviewed studies by making existing data more accessible to decision-makers (Yannascoli, Schenker & Baldwin, 2013; Bwanga, 2020). In this study, the researcher adopted purposive sampling, which is also known as judgmental, selective or subjective sampling. This is a sampling technique in which the researcher depends on their own judgment when selecting members of population to participate in the proposed study. When the researcher relies on their own judgement when choosing elements of the sample, it is called a non-probability sampling method or purposive sampling. Researchers often have faith in that they can gain illustrative sample by using a sound judgment, which resulted in saving time and money (Mokwena & Maluleke, 2020).

The seminal studies on this subject were purposively collected using keywords extracted from the research topic. Only sources of high academic standing, with integrated ideas, and not separate writings on this topic were reviewed. These studies were demarcated to recent studies (Not older than 10 years). However, other studies outside this projection provided greater significance to the research topic to offer relevance and trustworthiness (Mokwena, Motsepe, Maluleke & Shandu, 2020). Again, the researcher used the inductive TCA to analyse consulted textual materials and to collect as well as to categorise relevant data on this subject. Bryman (2012), Matthews and Ross (2010) and Maluleke (2020) agree that to achieve the TCA, the reviewed documents were regarded as something more than just a source of data, since it is possible to research documents in their own right as a ‘field’ of research.

4. STUDY FINDINGS AND DISCUSSIONS

Data that is presented in section 1 and 2.1 of this study, present the demand of medicinal plants in various levels of South Africa. Grunwald and Buttel (1996) (in section 2.1 of this study) stated that the demand for medicinal plants has been rising, which results in increased pressure on wild plant populations. This, and also the lessening of habitats in various parts of the country, means

that South African indigenous plants are now facing the risk of extinction on a local level. Fullas (2007) confirmed that, in various developing countries, including South Africa, medicinal plants play an important role for the primary health care purposes as presented in section 1 of this study. Williams *et al.* (2013) and De Wet *et al.* (2013) concurred that the majority of South African rural communities still prefer the use of medicinal plants for the purposes of their primary health care, in spite of the availability and accessibility of western medical care services provided by the government.

Williams *et al.* (2013) in section 2.1 of this study, further highlighted that people who migrate from rural areas to urban cities start to have limited access to indigenous plants. Therefore, they rely on street vendors and 'Muthi' shops to supply them with medicinal plants for their primary health purposes. It was also presented by Kasagana and Karumuri (2011) that the majority of people in rural areas depend largely on the natural resources that are found near them for the purposes of fuel wood and for medicine refer to section 1 of this study. It is also showcased by Ndhlovu *et al.* (2021) in section 2 of this study, that livelihoods of human population in rural and urban areas have a high demand for medicinal plants as they still perceive it as the main ingredient in traditional medical system and is an important source of human survival and well-being.

In section 1 of this study Van Wyk (2013) shared that approximately 50 percent of all pharmaceutical drugs around the world are produced from natural resource, and around 25 percent of them are medicinal plants. This, therefore, means that medicinal plants are used for different remedies. Moeng and Potgieter (2010) also stated that approximately 20 000 tonnes of indigenous plant materials, in a period of around a year, are used by South Africans as indicated in section 2.1 of this study. There are large quantities of these indigenous plants that are being commercialised mostly in informal 'Muthi' shops and 'Muthi' markets, which are usually harvested from wild populations. Furthermore, Van Wyk and Prinsloo (2018) in section 1 of this study hinted that in the history of South Africa, medicinal plants were the only primary source of medicines.

Maroyi (2013) in section 1 of this study also supported the notion that majority of people who use traditional medicines prefer them because of their affordability, easy accessibility and cultural acceptability. These authors (Bawa, 1993; Dovie *et al.*, 2002; Luoga *et al.* 2004) also stated in section 1 of this study that, when the human population grow the demand for medicinal plants also increases and the supply also attempt to compliment the demand. Thus, commercialisation of medicinal plants becomes the challenge of effectively managing the way in which people harvest these medicinal plants and the amount which they harvest and harvesters disregard conservation measures that are implemented for preservation of these.

It is also highlighted in section 2.1 of this study by Moeng (2010) that, despite the fact that most of South African rural areas have access to mobile clinics and other medical facilities, the service delivered seems to be insufficient in order for it to accommodate everyone and individuals believe that the usefulness of indigenous medicine is still effective, due to a natural distrust in anything that is Western and non-African. Furthermore, in section 1 and 2.2 of this study, data on the commercialisation of medicinal plants in South Africa is presented. Mander *et al.* (2007) presented that, the African Health Care System of South Africa has always been dependent of medicinal plants. On the other hand, Moeng (2010) also in section 1 of this study highlighted that this led to many people seeing a business opportunity to use these medicinal plants to generate income by commercialising them. Williams *et al.* (2013) showed that, during the process of the IUCN Red

List assessments, medicinal plants that were sold by ‘*Muthi*’ shops owners and street vendors were identified to be at high risk of becoming extinct as a result of this commercialisation.

In section 2.2 of this study Cunningham (1991) stated that the commercialisation of medicinal plants contributes to the multimillion-rand ‘hidden economy’ in southern Africa. Ndlhovu *et al.* (2021) concurs that the sales of medicinal plants in South Africa contribute both directly or indirectly to the economy of rural households through providing welfare and economic status. Furthermore, Wiersum *et al.* (2006) confirmed that the trade of medicinal plants is currently greater than it was in the past because of the important indigenous values associated with medicinal plants, the high human population growth and rapid urbanisation. Likewise, Moyo *et al.* (2015) indicated the challenge for medicinal plants for local trade and exploitation has been documented in different parts of the country over the years.

Section 2.1 of this study further provided that, as the demand of medicinal plants increase, so does the commercial demand (Street and Prinsloo, 2013). This also causes the destruction of medicinal plants gathering practices, and rising hereditary exposure to natural disasters, resulting in serious threat in the availability and supply of medicinal plants. It is also supported by Rasethu *et al.* (2019) that, one valuable source of income in many South African households in different provinces comes from trading of medicinal plants. Ndlhovu *et al.* (2021) in this case confirmed that some traditional health practitioners and indigenous knowledge-holders have taken an advantage to commercialise medicinal plants outside of traditional settings.

Additionally, Ndlhovu *et al.* (2021) opined that the commercialisation of medicinal plants in South Africa remains low, despite all the laws to conserve and promote the available medicinal plants. Ndlhovu *et al.* (2021) also shared that promotion of cultivation of medicinal plants under a participatory management action plan can stimulate the economy of the disadvantaged. Williams *et al.* (2013) in support mentioned that the commercialisation of medicinal plants and related products in South Africa is estimated to generate at least 134 000 income opportunities, since it is also estimated that approximately 72 percent of black South African population, including those that are living in urban areas still depend on medicinal plant to meet their primary health care needs while over 70 000 of medicinal plants are used per year in South Africa, this reads with section 2.2 of this study.

Williams *et al.* (2013) specified that, trading of medicinal plants are done through several large markets all over South Africa, particularly in the summer-rainfall regions. According to Ndlhovu *et al.* (2021) in section 2.2 of this study, the traditional medicine industry is unregulated, with an estimated contribution of the South African Rand [ZAR] 2.9 billion (United States Dollar - USD 192,948,107) to the economy per annum. Ndlhovu *et al.* (2021) also mentioned in section 2.2 of this study that, as a result, many rural communities resort to the use of traditional medicine as an alternative medicine, a trend that has been observed in urban areas where there are many ‘*Muthi*’ markets.

Section 1, 2.1 and 2.3 of this study corroboratively revealed that about the conservation of medicinal plants in relation to commercialisation is presented. Chen *et al.* (2016) in section 1 of this study confirmed that, overexploitation, indiscriminate collection of medicinal plants, high demand, as well as uncontrolled deforestation, affect their availability. Williams *et al.* (2013) in section 2.1 of this study stated that, South Africa became the only country that has evaluated the

conservation significances of its whole flora in the whole world, using the IUCN Red List guiding principles but with additional three more categories, namely, Critically Rare, Rare and Declining. According to Kasagana and Karumuri (2011), plant conservation is aimed at supporting the sustainable development of natural resources. It is that are implemented in order to preserve and protect these medicinal plants through employing methods that do not endanger the existence and availability of medicinal plants or methods that protect the important habitants and ecosystem from destruction.

Rasethé *et al.* (2019) in section of this study revealed that, gatherers of medicinal plant utilise different methods of harvesting of which some threaten the future existence of medicinal plants. Some of these methods are safe for the survival of medicinal plants. These methods include removing parts of the bulk, collection of roots, bulb, uprooting the whole plant, and cutting stems and leaves off. In section 2.3 of this study Rasethé *et al.* (2019) continued to state that, when the plant gatherers are collecting the large quantities of medicinal plants of conservation concern they use those harvesting methods. In some cases, they use methods of collection that are illegal in protected areas, and they critically place the ecosystems in danger.

Kasagana and Karumuri (2011) mentioned that, the '*In-Situ* and *Ex-Situ*' conservation are the two main methods for conservation of indigenous plant species. Kasagana and Karumuri (2011) contended in section 2.3 of this study that, in South Africa, the law enforcement approach was used for conservation of medicinal plants. However, this approach has failed evidently and that new, effective and participatory methods are required to protect medicinal plants. In response to the duty to respond to the overexploitation and threat of natural populations of medicinal plants, several efforts have recently been implemented to conserve the diversity of medicinal plants. Moeng and Potgieter (2011) in section 2.3 of this study pointed out that, Community-Based Natural Resources Management are responsible for the conservation of medicinal plants. Moeng (2010) continue to corroborate this statement by mentioning that, '*Muthi*' shop owners and street vendors play an important role in the trade of indigenous medicinal plants in South Africa, and it is important for them to develop strategies to prevent loss of these plants. In section 2.3 of this study, Van Wyka and Prinsloo (2018) supported that, the sustainable rate harvesting is determined by the category of the vegetation that is being collected, the kind of plants or parts of the plants that are collected, their richness and growth rates.

5. IDENTIFIED STUDY THEMES AND CHALLENGES

- **High demand for medicinal plants:** In section 2.1 of this study, Street and Prinsloo (2013), Chen *et al.* (2016), Williams *et al.* (2013) and Ndhlovu *et al.* (2021), collectively agreed that most communities depend on medicinal plants for survival, as well as to achieve their primary health care, and that this often increase demands of these plants, whether available on various markets, either legal or illegal.
- **Commercialisation of medicinal plants:** Street and Prinsloo (2013), in section 1 of this study, stated there are various factors contributing to growth of the South African economy, and that in an attempt to fight unemployment; selling of medicinal plants is touted as one of the active method to escape this reality. Therefore, thoroughly research on exploitation of natural resources found in the floral landscape is highly sought necessary, as indicated by Cunningham (1991) and Ndlhovu *et al.* (2021) in section 2.2 of this study.

- **Destruction of medicinal plants:** Chen *et al.* (2016) in section 1 of this study mentioned that habitat destructions [Destructions of medicinal plants] owing to the high demand for these plants affects their availability. Street and Prinsloo (2013) in section 2.2 of this study highlighted that; as the demands for these plants increase, so does their commercial demands, and the destructions of wild harvesting practices become a norm, and the vulnerability of these plant is commonly witnessed, owing to unregulated availability, supply and demands mechanisms.
- **Harvesting methods:** As indicated in section 2.2 of this study; Rasethe *et al.* (2019) supported that when ‘plant gatherers’ collect large quantities of medicinal plants for conservations, concerns are directed to harvesting methods, as in some cases the methods used are deemed to be illegal, as certain areas are protected and they are refereed as critically place for ecosystems, further posing a serious danger to the available medicinal plants, while, Street and Prinsloo (2013) in section 1 of this study also shared that overexploitation of these plants remains a serious threat to their availability due to current intensive harvesting processes relating to the existing high demands.

6. STUDY CONCLUSIONS AND RECOMMENDATIONS

The objective of this study was to interpret the commercialisation of medicinal plants in South Africa. This was done to reveal existing prospects and challenges. The study found that the majority of South African rural communities largely depends on the use of these plants for their primary health care purposes, positively leading to their high demands. This has consequently led to high rate of commercialisations. The findings of this study indicates two main reasons why people choose to commercialise medicinal plants. They are: 1) The high demand on their different valuable usage, and; 2) Opportunity to generate necessary income. In spite of western health care facilities available in South Africa, provided by the National government; the majority of individuals in rural communities continue to prefer the use of African medicinal plants for their primary health care. Lastly, due to the unemployment rate in South Africa, most of these individuals view the commercialisation of medicinal plants as an income generator.

It is hoped that this study can be used as a framework to educate relevant stakeholders and to also create awareness on the effects of commercialisation of medicinal plants. Furthermore, future research studies could be done relating to this subject to ensure preservations and protections of these plants. For the purposes of offering good practices of ensuring proper commercialisation methods of medicinal plants in South African rural communities.

Importantly, although an institution, such as the ‘CBNRM’ are introduced for the protection and preservation these plants, it is not always effective and successful in protecting some of the valuable plants. Studies on commercialisation of these plants strongly indicates that their commercialisations can endanger them, leading to extinctions. Subsequently, the issue of extinction of these plants is often recognised as a major problem across South African rural communities, as the issues surrounding commercialising these plants has been proven to be one of the existing threats to the availability of the remaining medicinal plants. As a resort, the following recommendations (Refer to Table 2) are made for possible implementations relevant stakeholders in this study field.

Table 2: Recommendations to improve study objective and the identified themes and challenges

| Study objective | Commercialisation of medicinal plants in South Africa |
|--|---|
| Identified study themes and challenges | Recommendations |
| High demands for medicinal plants | It is recommended that while recognising the high demands for medicinal plants in most South African rural communities, medicinal plants gatherers should not only focus on the associated profits; they should not neglect the importance of applying proper conservation methods. State what it is that they should do. |
| Commercialisation of medicinal plants | It is recommended that, responsible individuals should practice proper conservation methods, as proposed by the CBNRM. This can increase the prevention of loss of these plants and avoid future extinctions, which may subsequently lead to further losses of income. |
| Destruction of medicinal plants. | This study recommends that even though there are high demands of these plants, the medicinal plant gatherers should always use conservative ways of harvesting to prevent future and possible extinction. |
| Harvesting methods | This study recommends that medicinal plants gatherers should use proper harvesting methods that are safe in nature to ensure long survival of these plants, and to accomplish sustainable future usage. |

LEADERSHIP DEVELOPMENT AND SUCCESSION PLANNING IN MEDICAL FACULTIES: AN INTEGRATIVE LITERATURE REVIEW

B.S. Ngcamu

University of South Africa; Pretoria, South Africa

ABSTRACT

This article seeks to critically review the available literature on the challenges of leadership development (LD) and succession planning (SP); the essential personal, interpersonal, and cognitive capabilities; the content of LD; and the effectiveness and impact of coaching and mentoring programmes that should be incorporated into SP programmes. A hermeneutic framework was followed in this literature review study, where the study variables were searched, classified, mapped, and systematically analysed. The data gleaned from the sparsely available literature show the significance of mentoring and coaching programmes. These have a positive impact on faculties' performance, sharing of knowledge, decision-making, relationships among stakeholders and introduction of radical changes. A plethora of challenges triggered faculties to embark on LD and SP programmes, which seek to address structural inertia, inefficiencies in human resources (HR) departments and ineffectual leadership. The reviewed literature consistently suggests that personal, interpersonal, and cognitive abilities and the content that should be covered in medical faculties' LD programmes is meant to prepare existing or future leaders to ascend to leadership positions. This article paves the way for the HR practitioners and academic managers to understand the leadership challenges in medical faculties; the benefits of internal mentoring and coaching programmes; as well as illuminating the content, personal, interpersonal, and cognitive capabilities that need to be included in LD and SP programmes.

Keywords: Coaching; hermeneutic framework; leadership capability framework; leadership development; medical faculties; mentoring.

1. INTRODUCTION

Progressive universities across the globe have embarked on leadership development (LD) and succession planning (SP) programmes which have been influenced by the inevitable exodus of leaders, including the “baby boomers”, those approaching retirement age and millennials' high turnover (Azizollah et al. 2016; Figueron, O. 2015; Leibowitz et al. 2015; Viggiano, 2018). This presents difficulties in filling vacant leadership positions. In the meantime, the multifaceted challenges and leadership roles faced by academic leaders in medical schools have been acknowledged (Fernandez et al. 2020), with minimal effort to develop its prospective leadership pool (Gaur et al. 2020; Gigliotti & Ruben, 2017). This has been compounded by a lack of consensus on incorporating LD and management content in the curricula of medical qualifications. This has come about as a result of confusion on the modules and the learning outcomes to be included LD programme curriculum. The inadequacy of LD and SP programmes is evident as heads of department (HoDs) in the health fraternity have been recognised as being inept (Ngcamu, 2019).

As a result of the absence of buy-in from university leaders, the multifaceted nature of medical school departments requires skilled, adaptive, and prepared leaders to deliver pragmatic results. Furthermore, the leadership crisis in medical schools has been largely invisible to universities' leadership (Fernandez et al. 2020). This has been compounded by LD and SP programmes being unfocussed, with a tendency to proselytise. Consequently, Kiel (2015) terms LD as a specialised dimension of professional development which includes a host of competencies such as knowledge and skills that academic leaders need in ensuring there is effectiveness in the faculty. Succession planning, meanwhile, is regarded as a systematic method that includes forecasting, enabling talented leaders to be retained and developed to ensure leadership continuity and sufficient and efficient leaders for the future (Butler & Roche-Tarry, 2002; Fibuch & Van Way, 2012; Griffith & White, 2011). Nevertheless, LD and SP have not been simultaneously explored empirically in medical faculties, as proven by the dearth of research on this topic. The scarcity of credible research on these crucial variables on academic leaders was the motivation for the present study, to synthesise the existing but sparse body of accumulated literature. This area of research and practice needs a scholarly analysis to extend the existing literature; expose scholars to potential foundations; propose the development of a conceptual model; and identify areas of interest and focus for future researchers.

A host of challenges show more confidence in the lack of LD and SP programmes have manifested in medical schools (Ngcamu, 2019) across the globe, which includes an underinvestment in leaders (Dayan et al., 2014), with poor leadership having an impact on the poor coordination of programmes (Jooste et al., 2018). In addition, academic leaders in faculties lack support in terms of the development of essential skills and knowledge (Kiel, 2015) with competencies, skills and knowledge audits that are non-existent (Hargreaves, 2015). Little focus is given to medical academic HoDs (William et al., 2016: 465) and academic governance is inefficient (Bikmoradi et al., 2010). Previous perpetual conditions in medical faculties exist, with the full knowledge of university leaders that the HoDs who are employed in these crucial leadership positions are prominent academics. Nevertheless, they have minimal leadership and relevant management experience, with most of these HODs learning on the job (Detsky, 2011: 88; Garwe, 2014; Parrish, 2015). An investment perspective in LD has been suggested by Stephen et al. (2016), with an incremental return on the positive impacts of LD increasing performance. Spendlove (2007) suggests that SP should be intertwined with LD. Minimal empirical research has addressed this salient topic on LD and SP in medical schools, which calls for well-respected academics to examine the existing void in the literature. The background provided above sheds light on the significant association between LD and SP, which suggests that they cannot be explored separately.

Consequently, the objectives of the current study were achieved through the comprehensive analysis of 35 journal articles from credible electronic databases (PubMed, Emerald, SAGE, BMC Medicine, Taylor and Francis, Springer, and Wiley Online Library), in addition to a citation index in the discipline of medicine, education, social sciences and management. These articles were selected due to their high number of citations, with the articles having a total of 1818 citations. Essentially, broad literature associating LD and SP in medical faculties was researched. Once a faculty of interest was identified, an independent analyst classified journal articles that were within the scope of the study. Such research is essential since there is a scarcity of sound research on the

LD and SP of academic leaders in universities (Conger & Benjamin, 1999; McMurray et al. 2012; Ngcamu, 2019; Plavsic & Mulla, 2020).

2. METHODOLOGY

A hermeneutic framework (Boell & Cecez-Kecmanovic, 2014) was adopted to search, classify, map, and critically assess the literature where themes and arguments emerged. An MS Excel spreadsheet was developed where all the constructs were recoded for further screening, analysis, and screening assessment. The spreadsheet was perused to identify relevant studies that meet the literature review objectives of the study. The selected articles were then transferred to NVivo version 12, a qualitative analytical tool, for further analyses, coding, categorisation, and themes development, in the form of nodes to generate relevant patterns and themes. As the unit of analysis in this article focussed on LD and SP programmes in medical faculties of universities, the database search included these variables and were used interchangeably. Articles on LD strategies and succession plans for academic HoDs and deans were selected for analysis. Moreover, a simultaneous examination of the phenomenon being examined has implications for practice because university leaders will interchangeably incorporate LD programmes in succession plans. This in turn will yield positive results on the availability of leaders who have strong leadership traits in this tumultuous university context. Consequently, human resources (HR) practitioners will improve their systems, business processes and practices to ensure that leaders of calibre and talent are available during times of emergency and crisis in medical faculties.

Data search, capturing and analysis

The literature review followed an inductive grounded theory approach, leading to the search for relevant articles and official reports. This was followed by the codification, capture, and interpretation of the prevalent themes (McCann & Polacsek, 2021). The researchers pinpointed a host of relevant journal articles and some official reports that revolved around the objectives of the integrative literature study. This was produced from 88 articles, 8 book chapters and eight conference proceedings. The main keywords included were ‘leadership development’, ‘succession planning’ and ‘medical faculties in universities. This review study was theoretically grounded on empirical studies that focused on leadership development programmes and succession planning in universities. These journal articles and reports were retrieved mainly from the Google Scholar.

3. RESULTS

3.1 Leadership development framework

The institutional training evaluation model by Kirkpatrick (1996), adapted in this integrative literature review study, clarified the criteria and plans that are created by universities to assess the outcomes of LD programmes. Furthermore, it dissects the available literature on the feedback to internal and external stakeholders of leaders’ effectiveness post-training. The institutional training evaluation framework is divided into two parts: internal (reaction and learning) and external (behaviour and results) measurement criteria. The internal aspect focusses on what occurs during the training programme, whereas the external one focusses on changes outside of the training (Praslova, 2010: 220). The reaction criteria are critically evaluated in the LD discourse in medical

faculties in terms of participants' satisfaction after training programmes, their supervisors' evaluations, and self-reports.

This study further measures the learning outcomes for leaders (learning criteria) where various tests are used, including post-training measures of performance by their line managers and skills demonstration in the training context (Alliger et al., 1997). Moreover, the behavioural criteria measured on-the-job performance, the effects of training on work performance, and job outputs evaluated against set objectives (Arthur et al., 2003). The results criteria are followed where productivity gains, increased customer satisfaction, employee morale and an increase in the return on investment is evaluated in this study (Arthur et al., 2003). Under this ambit, the LD of participants is evaluated. This is done in terms of the impact on the employability of competent students who are responsible to local and global communities, as well as their contribution to the society (Sax, 2004).

3.2 Leadership development: Unpacking constraints

Medical faculties in universities across the globe have been faced with a multiplicity of challenges (Fernandez et al. 2020) which are largely attributed to its complex nature that requires multifaceted leaders who have multiple competencies and skills. Accordingly, leaders who are ill-prepared, with limited academic experience and inefficient leadership capabilities in faculties that offer LD programmes, are deemed unfocussed. The effects this has, also in addition to not being measured, are some of the challenges in medical faculties.

Collins-Nakai's (2006) perception of the Canadian Medical Association (CMA) on LD and whether there is a need for HoDs to be developed in medicine revealed that a need and a void do exist. In addition, Collins-Nakai's (2006) mentioned that the focus group members felt they are not equipped to ascend to leadership positions. These members felt they require leadership and management skills that are relevant and effective in their communities, professional associations and can influence policy.

According to Blumenthal et al., (2012), many clinicians are inadequately prepared to perform their clinical leadership responsibilities, and empirical evidence suggests that effective leadership yields better clinical outcomes. Jooste et al., (2018) mention the challenges that have been mostly attributed to the appointment of HoDs to leadership positions who have limited leadership experience. The university environment, however, is highly competitive, which requires strong leadership. This has been evidenced in different departments in medical faculties as physician leaders have insufficient knowledge and skills to lead (Dubinsky et al., 2015). Additionally, physician leaders have been found to lack understanding on how specialised schools are governed, led, and managed (Townsend et al., 2008) and leaders demonstrate a lack of formal education and leadership training (Evans, 2016; Hall, 2007).

Numerous researchers have observed the effects of poor leadership capabilities, which have led to the inability of organisations to optimise their quality, fundraising and other activities (Dubinsky et al., 2015) and a high turnover of employees (Evans, 2016). Dopson et al. (2016) have concluded that LD in medical faculties is unfocussed. These researchers suggest that the effectiveness of LD has not yet been explored empirically, compounded by difficulties in measuring its impacts. These authors further argue that the fields of measurement in university settings relating to LD is lacking,

with low reliable evidence and a theoretical base. These latter challenges are exacerbated by HR staff's lack of understanding of the critical cultures, time demands, academic structures and career trends (Cherry & Thorndyke, 2010). In addition, HR leaders tend to focus only on the LD of non-academic staff members.

3.3 Internal mentoring and coaching programmes in medical faculties

The results of fruitful internal mentoring and coaching programmes have been observed in medical faculties. Law et al. (2014) cited the Joint Council Task Force of the American Association of Colleges of Pharmacy (AACCP) on effective mentoring, which was responsible for collating information on best practices relating to the mentoring of existing and prospective leaders. The authors recommended that the roles and responsibilities of a mentor be clearly defined, discussed with the mentee, and expectations set at an initial phase. The mentorship approach should be formal and systematic, with junior staff members allocated internal mentors, and resources (time, technology, and funding) provided to staff members. Law et al. (2014) suggest that mentors considered in different stages of employees' careers and that data from previous programmatic assessments should be solicited to determine the success of a mentorship programme. One of the crucial LD methods is coaching (Tompson et al., 2008), which has been associated with the execution of rapid changes in faculties by leaders. Scott et al. (2008) further suggest that internal coaching practices contribute extensively to the development of employees, performance management and knowledge sharing. Internal coaching practices improved inclusive and transparent decision-making, with training and development being prioritised.

The ManpowerGroup Company (2012) has espoused a plethora of results brought about by coaching in organisations, which include improved relationships, teamwork, job satisfaction, and overall improved productivity and performance. Several researchers (Coutu & Kauffman, 2009; Hammoud et al. 2022; Gentry et al., 2008; McLeod & Steinert, 2009; Wolff et al. 2020; have shown the benefits of internal coaching that is incorporated with other LD programmes, showing measurable impacts that are positive, with many success stories. A coaching culture (Swensen et al., 2016), with effective managers who are capable of coaching leaders, have yielded positive results, including increased employee engagement and improved productivity and financial performance (Bersin, 2007). According to Swensen et al. (2016), strong coaching programmes result in improved organisational outcomes and teams that are agile. Kiel (2015) believes that leadership efforts for mid-level faculties can achieve a host of goals. These include:

- Succession planning
- The retention of minorities in faculties
- The break-down of silos
- Preventing problems
- Building relationships in the mid to senior level
- Implementing needed changes
- Increasing and fostering creativity and empowerment among mid-level managers
- Creating synergy in terms of the development of administrative leaders
- Encouraging dialogue.

Kiel (2015) further proposes that executive team-building strategies equip leaders with executive skills, something that should be implemented by university vice-chancellors. They should

introduce training for second-level leaders on institutional goals and ensure third-level departmental heads and directors receive training on coaching and facilitation services. Kiel (2015) suggests that the mode of instruction in these programmes should include a mix of simulations and assessments or face-to-face courses, webinars, and online programmes.

3.4 Strategies for leadership development and succession planning: A synergy

There are different perspectives and common themes regarding the association between LD and SP in university faculties. However, an advanced review of the literature sheds some light on the relationship between LD and SP by providing the benefits for an association. This has been noticed in a succession management (SM) project performed by McMurray et al. (2012). This study was conducted in a faculty of health academics in an Australian university, aimed at increasing stability in the university and equal opportunity goals, developing personal leadership capacity, promoting employee satisfaction, and providing motivation and mentoring opportunities. This programme covered pertinent topics such as decision-making, change management, communication, career development and self-management, and targeted employees who had an interest in occupying leadership positions. The programme consisted of weekly sessions. It followed Kirkpatrick's model to assess programme subjects' knowledge, change in behaviour, plans and reactions. McMurray et al. (2012) found at the end of the programme that the participants learned specific aspects of leadership knowledge (interpersonal skills and confidence) and observed changes in their perceptions of leadership roles going forward. These authors concluded that on-the-job-programmes on SM are more essential than ones conducted by independent consultants who do not have extensive knowledge of how universities function.

Accordingly, Dubisky et al. (2015) argue that healthcare organisations should offer LD programmes in collaboration with professional organisations and business schools to develop leadership concepts, skills, and competencies. Evans (2016) is of the opinion that proactive SP programmes play a crucial role in responding to the scarcity of leaders in the health fraternity, and nurse leaders are no exception. Evans (2016) suggests a succession committee as being pivotal in providing the continuity of leaders through SP. The author further claims that this is to prevent vacant positions and a high attrition rate; establish role competencies; develop methodologies to identify internal and external talent; and identify the tenure and turnover rate. The development of academic HoDs has been suggested by Jooste et al. (2018) to be conducted by professionals who are knowledgeable in formal and informal settings, with mentoring programmes and group meetings encouraged. These authors further recommend that leadership succession programmes should be context-specific, and the competent employees be selected to ascend to leadership positions.

Numerous studies in faculties of medicine have been performed on academic LD programmes. For instance, Loh (2016) conducted an inductive study by targeting 45 medical leaders, exploring their beliefs of the concept of the "dark side", and identifying the bottlenecks in such organisations. The research findings espoused the elements of the "dark side", which include a lack of managerial and clinical credibility, conflicts with clinicians and the complexities of medical leadership that is lacking among colleagues. In 40 medical schools in South Korea, a thematic research study was performed between 2007 and 2015 by Kim et al. (2017), which explored the characteristics that affect attendance at faculty development programmes. The themes that were identified included

cooperation, dealing with a changing future, and serving in various societies. A total of 30 deans were sampled in Canada, England, and Australia with nominated personal and positional attributes. These included having vision, passion, patience and courage, and the ability to facilitate, share and be supportive (personal attributes); and attributes that were positional (promoting nursing, strong management, role modelling and faculty development). A few factors were mentioned by Townsend et al. (2008) in leading effectively, including effective management, adequate and smooth communication, development, and motivation. Numerous recommendations were provided by the latter authors, such as the establishment of an advisory board in dental schools that focusses on leadership, management and governance, and an awareness of good communication.

Stephen et al. (2016) mention a strategy used to develop leaders at a Mayo Clinic. This included a central team-based development system, an egalitarian leader selection process, a patient-centred organisational design, and a collaborative leadership structure. A qualitative study by the same authors concluded that the foundations of leadership developed are organisational culture and design (Stephen et al., 2016).

A single qualitative case study was conducted by Ngcamu (2019) among nine HoDs in a faculty of medicine in a South African university. The aim of Ngcamu's (2019) study was to determine the challenges faced by HoDs, available succession plans, competence, and development programmes to develop future talent. The study findings revealed that leadership positions were dominated by employees at a post-retirement level, with competent and talented employees ascending to leadership positions aggravated by the non-existence of succession plans as well as developmental and mentoring programmes. The findings by Ngcamu (2019) further espoused the absence of the tools of the trade, structural fragmentations, and inefficiencies in the HR department. The author has drawn pertinent conclusions – that HoDs should be supported by the HR department, that broken HR processes be mainstreamed and that well-coordinated and structured development, mentoring and coaching programmes and succession plans be introduced.

A literature review study was conducted by VanVactor (2015) that afforded practising management professionals in a health fraternity with a model for SM and planning. This research expounded its impacts and provided the opportunity to mitigate organisational problems relating to attrition levels for leaders. This study has drawn some interesting conclusions about the costs, outcomes, processes, and procedures associated with healthcare organisations and relating to SM and planning. Ho (2016), O'Leonard (2014) and Schwartz et al., (2014) posit that skills development funding in organisations tends to be allocated to LD programmes, although such programmes are viewed by large organisations as being ineffective.

A synthesised literature review that was conducted with medical students on leadership and management competencies by Abbas et al. (2011) concluded that the subjects confirmed that LD education is essential and should be incorporated into their curriculum. VanVactor (2015) identified four seemingly intuitive aspects: the identification of leadership gaps and top talent, customisation development opportunities for employees who may be suitable for an organisation and the personalisation of onboarding practices. An inductive exploratory case study, conducted by Lieff et al. (2013) at the Canadian Faculty of Medicine on the intrinsic needs of HoDs, found that they required cultural and structural awareness to better understand the university and hospital

landscapes, employee support initiatives, exchange of information, strategy, infrastructure growth and development and improvements in both interpersonal and influence skills.

3.5 Leadership capability framework: Personal, interpersonal, and cognitive abilities

There are viewpoints from multiple perspectives on the leadership capabilities (personal, interpersonal, and cognitive) that are appropriate in the faculties of medical sciences in universities. The personal skills – which include emotional intelligence and support (Dubinsky et al., 2015; Lieff et al., 2013), effective communication (Dubinsky et al., 2015; Grigsby et al., 2009; Kiel, 2015), time management (Kiel, 2015), professionalism (Turner, 2018) and cultural awareness (Lieff et al., 2013) – are largely regarded as essential in LD programmes in medical faculties. In addition, Dubinsky et al. (2015) mention integrity, passion, judgement, and compassion as crucial traits, while Swensen et al. (2016) cite empathy, kindness, and support-engendering loyalty. The complexities and dynamics of medical faculties need leaders who have extremely strong interpersonal relationship skills as they deal with a myriad of sophisticated stakeholders with different interests and demands. A number of studies have suggested that leaders in such faculties should collaborate and network (Dubinsky et al., 2015; Grigsby et al., 2009; Kiel, 2016; Lieff et al., 2013). In addition, the following are also regarded as important: team orientation (Dubinsky et al., 2015), conflict resolution (Dubinsky et al., 2015; Grigsby et al., 2009; Kiel, 2016), emotional intelligence (Dubinsky et al., 2015; Lieff et al., 2013), communication (Dubinsky et al., 2015; Kiel, 2015; Grigsby et al., 2009), influential persuasiveness (Kiel, 2015; Lieff et al., 2013), mentoring (Dubinsky et al., 2015) and interaction with senior management (Scott et al., 2008). Leaders are supposed to be competent in core business skills, including clinical work (Dubinsky et al., 2015), and research and education (Dubinsky et al., 2015; Scott et al., 2008). There are also essential knowledge-focussed areas that leaders should know and practice. These include strategic thinking and planning (Dubinsky et al., 2015; Evans, 2016; Grigsby et al., 2009; Kiel, 2016; Lieff et al., 2013), building strategic partnerships (Dubinsky et al., 2015; Schwartz & Pogge, 2000; Schwartz & Souba, 2000), organisational awareness, management, dynamic industry knowledge (Dubinsky et al., 2015; Turner, 2018), and financial planning and budget monitoring (Dubinsky et al., 2015; Kiel, 2016; Scott et al., 2008). The following are crucial in LD programmes: innovation (Dubinsky et al., 2015); conceptualising and implementing innovative programmes (Dubinsky et al., 2015); being flexible and willing to adapt to change (Kiel, 2016; Swensen et al., 2016); managing performance, compliance, information technology and data security, and contracting and purchasing (Kiel, 2015); and having structural awareness (Grigsby et al., 2009; Lieff et al., 2013). Furthermore, diversity management, understanding large and small group systems (Kiel, 2015), cultural awareness, knowledge sharing and solving adaptive challenges (Grigsby et al., 2009; Lieff et al., 2013) are needed in dynamic academic medical faculties.

3.6 Content and effectiveness of leadership development programmes

The effectiveness of leadership training in organisations was questioned by Lacerenza et al. (2017) by performing a meta-analysis to estimate the effectiveness of training across four criteria: learning, behaviour, reaction, and result (Kirkpatrick 1959). Out of the 335 sampled respondents, the results showed leadership training as being more effective, which led to improvements in reactions. A study by Collins (2002), meanwhile, viewed a total of 83 studies that provided formal training interventions to leaders using a meta-analytic technique. The aim of Collins' (2002) study

was to determine the effectiveness of the interventions in improving their individual, team, group, or organisational performance, knowledge, and expertise. The commitment was seen in these organisations as strengthening their leaders through training on skills, perspectives, and competencies. The results of this study showed formal training programmes with knowledge outcomes to be highly effective (Collins, 2002). Another empirical study testing the relationship between team techniques and team outcomes, by Salas et al. (2008), found that interventions based on teams in organisations improve cognitive, effective team outcomes, and team processes and performance outcomes in organisations. Meanwhile, a systematic review study by Leskiw and Singh (2007) on the development and assessment of best practices in LD strategies and programmes found six key factors that were vital for LD effectiveness. These include a meticulous needs assessment, a suitably selected audience, the design of relevant infrastructure to support initiatives, the design and implementation of the entire learning systems, a credible evaluation system, rewards strategies to change, success and improvement deficiencies.

Consequently, several medical faculties have embarked on the development of academic leaders, although the content and focus areas vary. Wilkes et al. (2013) posit that LD programmes that are university-based and directed toward the faculty are gaining prominence in universities. The authors cited examples from LD programmes which have been initiated and implemented by a myriad of faculties of medicine in universities, including the University of California, the University of Minnesota Medical School, the University of Texas, the University of Washington, and the Cleveland Clinic Academy. These programmes, as per Wilkes et al. (2013), cover a host of pertinent topics related to leadership and which are relevant to leaders in the health fraternity.

On 4 April 2017, the Uniformed Services University of the Health Sciences (USA) LEAD team convened an inaugural Medical Student LEAD Summit and Working Group Meeting, with participants coming from both public and private medical schools involved in LD programmes. The rationale for the summit was to share opinions, experiences, and current practices regarding medical student LEAD programme (Grunberg et al., 2018). The participants agreed that LEAD is a significant component to be incorporated into an undergraduate medical education curriculum, but that the single best LEAD programme for all medical schools is non-existent. A clear purpose, goal philosophy and conceptual framework that is consistent with the mission and vision of each institution is essential. Research and scholarship, the assessment of students, and programmes and faculties must be incorporated as they are important in LEAD programmes.

Some researchers have considered a myriad of approaches in designing and implementing leadership programmes in the health sector. These include service design, business development, the patient experience, improving patient access, change readiness, leadership in primary care, primary care and programme or project methodology (Dubinsky et al., 2016). Swensen et al. (2016) recommend several LD approaches that involve assessments, programmes, stretch assignments or institutional projects, and coaching for physicians and leaders, which can enable the Mayo Clinic to live its mission and achieve its vision. Furthermore, the authors cite topics for LD at the Mayo Clinic, including overall strategy, lean six-sigma, change management, failure modes, effects analysis, project management and champions training. Grunberg et al. (2018) highlight a lack of consensus on the following aspects: the need to teach LD in medical degrees, unclear content to be covered, who teaches it and where it fits into the curriculum.

3.7 Generalisation of the main statements

The critically reviewed literature above on the development of leaders in faculties of medical sciences in universities focusses on a lack of leadership capabilities, which leaves a void in the literature. There are salient, relevant, and independent variables that have been overlooked by previous researchers, such as the role of university policies on training and development, university strategy and the performance management system's effect on providing relevant LD programmes in medical faculties. Furthermore, previous authors investigating the challenges brought about by internal or external mentoring and coaching or consultants, and internal versus external LD programmes, were blindfolded with less transfer and sharing of knowledge to the internal staff members and without any positive impacts seen. The capacity of HR practitioners to offer training and development functions and provide the relevant LD programmes that respond to the departmental, faculty and university strategic needs that address competency, skills and the knowledge gap have been overlooked by the previous researchers.

The sparse literature on the impacts of internal mentoring and coaching programmes in medical faculties have been critically reviewed; however, there is little evidence in the literature that cites medical faculties where such programmes have been implemented. Consequently, this leaves a serious gap in the literature which needs further exploration.

The literature reviewed in this study suggests that the available empirical data is largely qualitative, with no evidence of quantitative or mixed methods being used by previous authors. Gleaned from the synthesised literature above are similar challenges in both LD and SP, suggesting that the previous variables (LD and SP) cannot be explored or applied differently in medical faculties. The SP process encapsulates the attributes of LD. For instance, the literature reveals that both programmes are initiated and implemented because of a leadership vacuum in academic faculties, structural inertia and leaders being insufficiently prepared. Both LD and SP goals are to prepare prospective leaders through various training and developmental programmes. A critical analysis of the two variables has not been undertaken empirically, which confirms the need for this literature review study and to display this void. Nevertheless, the literature is absent in clearly linking leadership capabilities to LD and SP and its subsequent impact on leadership in medical faculties.

In addition, serious gaps have been noticed in the reviewed literature regarding the content that should be covered in LD programmes. For instance, an academic HoD should focus on strategy formulation and implementation for the department; they should manage performance and budget, ensure quality assurance, supervise reporting, M&E, and oversee mentoring and coaching, which are not mentioned by authors above. Furthermore, managerial competencies (soft and hard skills), which should be attained by leaders during LD, as well as knowledge of the business processes, systems, and structures, are a serious limitation in the previously published research studies.

4. DISCUSSION

The available (mostly qualitative) literature on LD and SP programmes in medical faculties in universities across the globe is contrary to Kirkpatrick's (1996) criterion to assess participants' reaction to learning and the outcomes of the latter programmes. The participants' reaction and learning during LD training and their behavioural changes towards their daily work activities post-

training is not evident. This is because the measurements are not followed as espoused in the literature above. The reviewed literature does not provide evidence on tests conducted with participants' line managers regarding the effects of LD programmes and improved productivity and performance. The research study's proposition – that leaders in faculties are not adequately prepared to occupy academic leadership positions in medical schools – agrees with a host of researchers who have observed this void in universities (Blumenthal et al., 2013; Collins-Nakai, 2006; Dubinsky et al., 2015; Evans, 2016). Consequently, the mentoring and coaching programmes in medical faculties have been associated with improved performance, knowledge sharing and radical changes by numerous researchers (Law et al., 2014; Scott et al., 2008; Swensen et al., 2016; Tomson et al., 2008). Furthermore, medical faculties that have embarked on succession plans have seen an improvement in interpersonal skills, confidence among leaders and positive change in behaviour, which has been supported by numerous scholars (Evans, 2016; McMurray et al., 2012).

However, some researchers (Dopson et al., 2016; Ho, 2016; Schwartz et al., 2014) have opined that significant funds have been invested in irrelevant and haphazard LD programmes, with less effect in operations in medical faculties. The personal, interpersonal, and cognitive capabilities that are mostly separately applied by leaders in universities have been cited by Lieff et al., (2013) Dubinsky et al., (2015), and Kiel (2016). to be central to leading medical faculties in universities. These authors further cite less anticipated capabilities, such as emotional intelligence, partnerships (with internal and external stakeholders), mentoring, and managing performance and compliance. Finally, LD programmes vary in universities, with researchers alluding to unique content in different medical faculties (Dubinsky et al., 2016; Swensen et al., 2016), with Grunberg et al. (2018) noting that there is no consensus in medical faculties on whether LD should be ingrained in the undergraduate curriculum.

5. CONCLUSION

The synthesised literature on LD and SP in faculties of medicine show that LD does not lead to improvements in reactions, learning and results (Kirkpatrick, 1959) since programmes are unfocussed and sporadic. Furthermore, the available LD programmes in faculties do not measure the impacts of training. There is limited reliable evidence showing a positive change in leaders regarding the performance of a team, faculty, and university, as well as satisfying both internal and external stakeholders. However, the literature on LD does meet the behavioural criteria (Kirkpatrick, 1959) as the benefits of coaching and mentoring in such complex faculties have yielded positive outcomes by measuring the effects of training (on-the-job) on work performance.

As a result, a myriad of themes have emerged in this synthesised literature study on the effectiveness and the impact of SP and LD programmes in medical faculties. The critically reviewed literature in this article demonstrates the similarities in the challenges facing medical faculties in initiating and implementing LD and SP programmes. It has been noticed in the literature that both LD and SP programmes have similar expected constraints, outputs, and benefits. This further suggests that future researchers should conduct empirical studies concurrently in medical faculties at different universities. This is because not much research has been conducted associating LD and SP as both programmes have similar characteristics and expected outcomes. Internal coaching in medical faculties has been considered to have brought

about multiple benefits to leaders, departments, and faculties. Therefore, few studies have been conducted to measure its impacts on faculty performance and change in organisational culture.

Furthermore, scholars have mentioned multiple capabilities leaders need to possess and which are specific to medical faculties. More in-depth reviews are essential in terms of detailing the personal, interpersonal, and cognitive capabilities critical faculties and its associated impacts on effectiveness and efficiencies. Both LD and SP programmes will continue to play a crucial role in medical faculties by identifying current or prospective leaders' deficiencies and managerial incompetence, while initiating and implementing responsive and focussed programmes. However, this can be achieved if quantitative research studies are conducted in these faculties by testing leadership capabilities. This is because previous and current studies that have been conducted and published are largely qualitative. A gap in existing literature suggests that future researchers should perform quantitative research studies in medical faculties by linking LD and SP as an emerging theme in health faculties. This study further provides a base to guide future researchers on the gap identified in the literature.

A skills leadership audit should be performed by qualified and accredited specialists where scientific tests are performed to identify suitable prospective leaders who can undergo blended leadership trainings. The faculty deans, together with training and development practitioners, should periodically assess and measure the impacts and outcomes of such trainings as it relates to the university business and the individual change in achieving the goals of the faculty and university. In view of the above, it is suggested that the faculties of medicine in universities blend various training strategies for current and future leaders. This they should do by combining LD, SP, coaching and mentoring programmes to improve organisational performance to society at large. The point of departure should be on developing systems to identify employees or leaders who can undergo blended training and be allocated managerial duties as a form of experiential learning.

A SYSTEMATIC SYNTHESIS OF LITERATURE ON WOMEN'S WORK–LIFE BALANCE IN AFRICA

B.S. Ngcamu

University of South Africa; Pretoria, South Africa

ABSTRACT

Work–life balance among the female workforce is a novel and seminal topic in developed countries, something that is rarely studied in Africa and which is generally in its developing phase. Although this topical field is under-researched in Africa, extant literature has failed to unearth the effects of work–life imbalance on the quality of work life of women in the workforce. From the foregoing, this literature review study is geared towards synthesising the current literature published, dissecting the effects of the work–life imbalance on women's employment conditions (productivity, performance and their small scale businesses) and examining the sustainability of their families. A hermeneutic framework was followed to search, categorise/classify, map and assess the previously published literature on work-life balance and its effects on women's Quality of Work Life (QoWL) in African organisations. A total of 346 journal articles were retrieved from different databases; of these, 16 were aligned with the study's research objectives. These articles were analysed, and themes and patterns were generated.

Keywords: Adaptation strategies; productivity; stress levels; quality of work life.

1. INTRODUCTION

Women in Africa are struggling to balance their work and life roles due to the inherent and unreasonable demands which adversely affect both their Quality of Work Life (QoWL) and Quality of Life (QL). In the 21st century, workplaces in Africa are still male-dominant, patriarchal and inflexible to women's needs. This has created unfavourable working conditions. In addition, women tend to work long hours, adversely affecting their QoWL and exacerbating the work–home imbalance. This has been consistently observed in different sectors in Africa where women experience an overload at work and at home due to the inherent demands on them. They experience unreasonable time frames and home responsibilities, which include their function as caregivers to their children and extended family members, in addition to their role in societal events (such as funerals, weddings and traditional gatherings). This has had adverse impact on their performance and productivity at the workplace and has compromised their well-being. There is a void in the existing published literature on Work–Life Balance (WLB) among African women in a number of sectors. In addition, there has not been a published study that has critically synthesised WLB and its effects on African women's QoWL. This literature review article therefore examines the existing literature on WLB as a novel concept among African women in various sectors. The literature review is rudimentary in terms of closing the gap in existing literature. This it does by unearthing the themes, patterns and trends in the published literature on WLB and its effects on the QoWL of women in the workplace in Africa.

Women's successes in various sectors in Africa have been hampered by an institutionalised, biased patriarchy (Adisa et al. 2016). There are countries that are known to have a patriarchal society,

such as Ethiopia (Gudeta & Van Engen 2018) and Nigeria (Ogunsanya & Olorunfemi 2012). The latter authors mention that women in Nigeria are discriminated against, which poses unnecessary pressures at work.

Numerous researchers (Adame et al. 2016; Allen 2002; Nwagbara 2020; Voydanoff 2004) conceptualise WLB to be employees' satisfaction, well-being, sustainable employment, lower stress, balance and effectiveness in their role at work and in the family. These researchers allege that these factors are compatible and that the various roles can function harmoniously. Durodolu and Mamudu (2020) opine that a good WLB occurs in a situation where a balanced relationship is established between private and professional life, without one negatively affecting the other. Quality of Work Life, meanwhile, is conceptualised as conditions that enhance employees' satisfaction, rewards, job security and growth opportunities (Zhao et al. 2013). Ogundanya and Olorunfemi (2012) are of the opinion that the approach to the motivation of female employees is achieved through the implementation of QoWL programmes, which can improve productivity. A host of researchers (Durodolu & Mamudu 2020; Shaikh et al. 2019) believe that WLB has attracted focus due to economic, political and cultural value systems, work overload, protracted working hours, the utilisation of technology, and challenges in managing the family, thus increasing the emphasis on productivity and job satisfaction.

An imbalance between work and family life among women in the workforce can have an impact on the two conflicting roles and negatively spill over into their personal lives. This can lead to the disruption of spousal relationships, increased stress levels, burnout, loss of enjoyment, health problems and job exhaustion (Akuamoah-Boateng 2020; Dlamini, Shakantu & Kajimo-Shakantu 2013; Jamal 2007). A plethora of researchers (Abubakar 2018; Duxbury & Higgins 2015; Jackson & Fransman 2018; Mushfiqur et al. 2018) have observed that women in Africa have been overloaded at their workplaces due to their devotion to multiple and diverse non-work functions (including as caregivers to children and the aged, and their responsibility for domestic chores). Consequently, women in Africa are believed to work longer hours that exceeds the contractual agreement. This is because their respective countries' labour legislations are less likely to offer flexitime (Akuamoah-Boateng 2020; Ebbers and Piper 2017; Jackson & Fransman 2008; James, Rust & Kingma 2012).

Meanwhile, other researchers (Chimote & Srivastava 2013; Mušura, Koričan & Krajnović 2013) have associated WLB with job satisfaction, an increase in productivity, the retention of female staff, low absenteeism and turnover, a reduction in stress and an increase in loyalty, autonomy and image. Iyabode and Olayinka (2016) found that women of a younger age in Africa manifested a significantly higher level of turnover intention and absenteeism than working women who are more mature, which has led to a brain drain. In the most complex industries such as construction, James et al. (2012) have found WLB amongst women to have increased organisational effectiveness and individual performance. Fong and Kwork (2009) attest to this viewpoint – that the operations in the construction industry are complex, with difficult conditions: stressful, with unreasonable time frames and poor working relationships. There are also other complex and challenging professions such as the medical field where women (mostly doctors) experience job stress and are negatively affected by the inequalitarian culture caused by inherent demands and challenges in balancing work and non-work-related activities (Aslam, Jamil & Tariq 2014; Lewis & Humbert 2010; Mushfiqur et al. 2018). Furthermore, in competitive and volatile industries such

the banking sector, women in Africa playing significant dual roles at work and in the home poses some challenges (Oladayo & Leah 2014).

In addition, women in Africa are the driving force behind the informal sector (entrepreneurship) because it has influenced them in working in this sector due to its flexibility, allowing them to manage the work–life interface better (Tremblay & Genin 2008). Annink and Den Dulk (2012) opine that women who are self-employed realise the desired autonomy, flexibility and control. However, Brush, De Bruin and Welter (2009) posit that more extant research is needed on women’s entrepreneurship in Africa to include family and household dynamics. Inequality exists in job placement, promotion, decision-making, responsibilities and trade union activities. The World Bank Group (2019) reported that in Nigeria, more men are employed than women. This has been supported by the Nigerian Bureau of Statistics (2018) – that only 38% of women are employed compared to 62% of their male counterparts.

There are two literature review studies that the researcher came across that have been published on women in the workforce in Africa. One of the studies focused on the influence of organisational culture on WLB in the construction industry (Dlamini et al. 2013) and the other, by Vettori and Nicolaidis (2019), synthesised the pay discrimination in the hospitality industry in South Africa. The current study closes the existing gap on the scarce scholarly articles that have been published. This it does by synthesising the existing literature on women’s WLB in Africa, and challenges and interventions to improve the balance between work and family life. The article further dissects the causes of such imbalance and the influences it has on effectiveness, efficiencies, productivity and businesses owned by women.

2. METHODOLOGY

The systematic literature review was planned, carefully executed, and recorded according to the hermeneutic framework. The latter framework by Boell and Cecez-Kecmanovic (2014) was followed in this literature review study in the search for secondary data sources, where it was classified, mapped and assessed to generate themes, patterns and trends. The previously published journal articles (16) investigating the WLB and QoWL of women in various sectors in Africa was considered to be relevant and was selected for further analysis. Only published journal articles that measured the WLB effects on the QoWL of female staff members in different sectors in Africa were considered.

2.1 Search Strategy

The researcher for the current synthesis of the previously published literature on WLB was supported by an experienced librarian specialising in the management sciences discipline in search strategy development. A planned and systematic search was performed between 01 June and 28 August 2020. The journal articles were retrieved from a variety of electronic bibliographic databases, and databases from different disciplines and websites. These included Google Scholar, Elsevier, IUP Publications, Academic Journals, AOSIS, ASCE Library, Emerald Insight, Technium Science, Cambridge Scholars Publishing and ICERM. The keywords that were used in a search engine were “quality of work-life for women in Africa” and “work-life balance for women in Africa”.

These keywords and themes were identified and retrieved to generate insight into WLB effects on the QoWL. A spreadsheet in Microsoft Excel was created where relevant article titles and author names were codified for screening, analysis and screening assessment. Only published studies on the WLB and QoWL of women in the workplace in Africa were retrieved and downloaded. The available, relevant, peer-reviewed articles were published between 2000 and 2020 – technical reports and theses that had been written in English. There were journal articles that focused on the WLB and QoWL beyond the African continent, which were considered to be irrelevant and excluded. Furthermore, master's and doctoral theses were excluded in this study. The selected journal articles that were most cited, according to the high-impact factors, were scrutinised, analysed and categorised where themes, patterns and trends emerged.

3. FINDINGS

This section systematically reviews the literature according to three themes: WLB effects on the women's workforce in Africa; work–life imbalance on productivity; and businesses owned by women.

3.1 Study characteristics

The synthesis of the literature review recorded a total of 16 relevant, published, peer-reviewed journal articles from 346 studies. A total of nine journal articles were tested using deductive theory testing (quantitative) and five were tested using inductively theory generation (qualitative). There were only two literature review studies that did not solely focus on the WLB effects on women. The majority of countries that published and which were found in this study were from Nigeria (9), followed by Ghana (2), Ethiopia and South Africa. There were several different sectors in the sampled studies, some of which focused on higher education institutions, financial institutions, entrepreneurship, the police force and the medical field. The majority of the selected studies focused on the extent to which the female workforce balance work and their families in different organisations. There are very few studies that focused on their QoWL and the impact on WLB. There are empirical studies that have been cited in the present study which support the articles listed in Table 1 (see below). Some of the cited articles in the text did not fully meet the initial selection of research focusing on the WLB of women in Africa.

Table 1: The study characteristics.

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |

| Akuamoah-Boateng 2020 | Quantitative | Convenience sampling technique n = 32 (female staff members) University of Cape Coast, Ghana | The study ascertained the extent to which the female workforce of the College of Distance Education balanced the roles of work, home and personal life. | The tight work schedule enabled the female staff members to balance their work, family and personal life; women exceeded the legal working hours per day (eight); allowances for flexi-time are non-existent; there are no policies and programmes available to develop women in terms of their WLB; family challenges have interfered with women’s work activities, which has affected their performance and productivity; their family commitments have led to women being penalised during performance measurement periods; family responsibilities have disadvantaged women and led to them being overlooked for challenging work projects; and they are unable to fulfil their social lives (such as attending church, weddings and funerals, and pursuing leisure activities). | The university does not develop policies and programmes that support women; the institutional policies and programmes that are pro-women employees are recommended; the university should create a conducive environment that promotes a healthy work–life interface. |

|-------------------------|-------------------------------------|--|--|---|---|
| Jackson & Fransman 2018 | Quantitative | Convenience sampling technique n = 252 (female support staff) University in the North West province, South Africa | To determine an association between financial well-being, flexitime and productivity; WLB and job satisfaction; employees' financial well-being, flexible work and work-life in terms of productivity; and job satisfaction and the mediating effects of productivity on the latter variables. | A strong association was found between financial well-being, WLB, and productivity and job satisfaction. | The main predictors of job satisfaction are financial well-being, WLB and salary increases for employees. Improving the WLB might result in a better understanding of the low levels of job satisfaction and result in fewer instances of low productivity. |
| Dlamini et al. 2013 | Literature review | n/a | Synthesis of the literature to determine the effects of organisational culture on WLB in the construction industry. | There is a strong association between the organisational culture and WLB for women; women are considered to work twice as hard as their male counterparts to prove their value and worth in the organisation; work-life conflict is possible among women; and the organisational culture prevents the effective implementation of WLB policies and practices. | Ordinary, illiterate and poverty-stricken women accept the conditions to satisfy their basic needs without recognising the significance of WLB; health policies should be formulated and executed in order to realise a healthy WLB. |

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |
|-------------------------------|-------------------------------------|--|--|--|--|
| Akanji, Mordi & Ajonbadi 2020 | Qualitative | In-depth interviews n = 52 (female medical doctors) Nigeria | The experiences of women's WLB, the causes of work-life imbalance, associated stress and adaptation strategies for medical doctors in Nigeria are assessed and informed by a spillover theory. | The work-home interference is aggravated by time pressure; sources of stress and work-family conflicts, which emanate from patriarchal proclivities and disparities in remuneration. | Female doctors cope with adverse WLB by developing individualistic coping strategies to mitigate the impacts; their inability to dedicate more time to their families is due to the organisational culture of rushing through their work, the associated stress and having limited time, which results from the job demands and long working hours; adverse work-family interference is attributed to poor infrastructure (poor roads); patriarchy; inadequate doctors; and inadequate medical facilities. |
| Adom et al. 2017 | Qualitative | Purposive sampling n = 25 (female entrepreneurs) Ghana | To evaluate how the female entrepreneur's work-family life influences business performance in Ghana. | The female entrepreneurs felt that their family roles and responsibilities have an adverse effect on their generated income and the willingness to expand their businesses. | Women strategically conduct their businesses in their homes or in close proximity or a combination thereof; women support their families through the income generated in these businesses; they are unable to expand or open other branches due to the needs of childcare and home management. |

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |
|----------------------------|-------------------------------------|---|---|--|---|
| Gudeta & Van Engen 2018 | Qualitative | In-depth interviews n = 31 (female entrepreneurs) Ethiopia | An exploratory study on understanding female entrepreneurs' challenges on combining work-life responsibilities. | A strategy on work-life boundary management – called integration – has been imposed on female entrepreneurs due to lofty expectations from other women to take care of family and social responsibilities; managing staff members at home demands that women combine their work and life roles and integrate more. | Women integrate their work-life social roles and eliminate the boundary between work and life; women's choice of boundary management style is not selectively influenced by normative societal expectations on them; they need to fulfil community obligations while managing and growing their business. |
| Iyabode & Olayinka 2016 | Quantitative | Descriptive and cross-sectional survey n = 265 Nigeria | A role conflict on women's QoWL and turnover intentions is examined in private organisations. | There is a strong correlation among the major variables of the study. For instance, a strong association was found between family-work conflict and QoWL, family-work conflict and turnover intentions, and work-family conflict and turnover conflict. | The results suggest that the low retention rate of women in the private sector workforce can lead to a brain drain; government initiatives and interventions in the form of policies to focus on women's welfare is required. |
| Oladayo & Leah 2014 | Quantitative | Descriptive cross-sectional survey n = 220 (female bankers) Lagos, Nigeria | It examines the effects of the work schedule on the family life of married female bankers in Nigeria. | These women are considered to be good dual career women; their WLB has directly and indirectly affected their active involvement in domestic and family functions; the balance between family and work is a major challenge for them and has created costs. | The married women spent a maximum of 15 hours per day at the workplace and less quality time with their family; they considered their work demands to be abnormal and were unable to balance work and home; there was a willingness to sacrifice their career in the interests of the family. |
| Ogunbamila & Idemudia 2016 | Quantitative | Cross-sectional survey n = 588 (193 females and 395 males) Nigeria | An investigation on the gender differences in QoWL for the police workforce. | The male police workforce had a better understanding of their QoWL as compared to their female counterparts. | Training was suggested for women in order to promote their QoWL. |

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |
|-----------------------------|-------------------------------------|--|--|---|--|
| Ogunsanya & Olorunfemi 2012 | Quantitative | Survey n = 3640 (senior women in four universities) Lagos, Nigeria | The organisational pressures of QoWL of women in Nigeria was investigated. | To improve the QoWL of women in universities, such institutions should focus on the factors, which create pressures and stress (absence of child care centres, extreme workload and unreasonable/long working hours); factors that increase women's dissatisfaction at the workplace should be considered; the marginalisation of women in decisions pertaining their well-being, limited access to the internet, insufficient healthcare facilities for them and their dependants and a lack of acknowledgement of their performance need to be addressed. | In order to improve productivity in universities, government and the executive committees of universities need to reduce organisational pressure and enhance the QoWL of the female workforce. |
| Person, May & Mayer 2016 | Qualitative | Semi-structured interviews n = 6 (women occupying senior positions and without children) South Africa | A study to understand what women attribute to their work in a South African context. | Once women experience autonomy at work, their meaning of life changes; working women reported a sense of identity and self-worth, meeting instrumental needs, achieving social relatedness and being of service to others. | The meaning of work is influenced by intrinsic satisfaction, a sense of power and authority. |

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |
|-------------------------------|-------------------------------------|--|---|---|--|
| Stella, Paul & Olubusayo 2014 | Quantitative | Comparative case studies in-depth case analysis n = 586 (managers and employees in the banking sector) n = 530 (education sector) n = 507 (power sector) Nigeria | The concept of WLB policies and practices has been investigated in three different sectors (banking, education and power); WLB initiatives have been unearthed and the hindrances in the implementation of WLB programmes identified. | There were diverse views on how the WLB concept is understood by the research participants; an extreme gap is observed between industries' understanding of WLB practices and the workforces' understanding of the concept. | Policies on WLB should be included in the organisational strategic plan; improving efficiencies and effectiveness, flexible working patterns should be provided by organisations; WLB programmes in the banking sector should be adopted, which has the potential to reduce the turnover rate. |
| Nwagbara 2020 | Qualitative | Interpretative approach semi-structured interviews n = 25 Nigeria | An association between WLB policies and practices as well as the challenges encountered by female employees in Nigeria is examined. | The unique institutional context and policies in Nigeria pose challenges to women; organisational and sociocultural pressures on women contribute to the women challenges | Institutional policies and practices favour patriarchy |
| Durodulu & Mamadu 2020 | Quantitative | Positivist research paradigm quantitative structured questionnaires n = 80 Nigeria | Research on the influence of WLB among the library staff members at the Kenneth Dike Library and the effects on the provision of information. | The research findings concluded that female librarians experienced a poorer WLB as compared to their male counterparts; their marriage status did influence their WLB on job-related activities. | The culture of prejudices against women (librarians) was confirmed in this study, which has adverse consequences on their productivity and career progression; even while women are as competent as their male counterparts, men receive more recognition |

| Article author/s | Design and methodology of the study | Study sampling and setting | Objectives | Results/Findings | Specific impacts on the well-being of women in the workplace |
|----------------------------|-------------------------------------|---|---|--|---|
| Vettori & Nicolaides 2019 | Qualitative | Literature review | The laws and the codes of practice as well as the applicable international laws regulating the pay discrimination are documented in this literature review article. | The hospitality industry is rife on gender pay discrimination; women are precluded from “breaking the ceilings” due to gender-based stereotypes and fallacious notions; the majority of women in the hospitality industry are women. | In the workplace, the female workforce should be supported in ensuring there is a balance between work and their personal lives; the hospitality industry should ensure that there are equal opportunities for upward mobility; interventions are needed to avert gender-based discrimination, lack of diversity and transformation; the South African Government has amended the Employment Equity Act to ensure that there is gender pay equality; the remuneration for equal value has been effected in the labour legislations amendments of 2015, which seeks to clarify the valid points for pay discrimination and processes to be followed to prevent and eliminate pay discrimination. |
| Ogungbamila & Olaseni 2019 | Quantitative | Cross-sectional survey design n = 944 (police) (429 females and 515 males) Lagos, Nigeria | The relationship between at which level is gender moderates the relationship between job demand and the police’s QoWL. | The research study revealed the significant decrease of the police’s QoWL due to job demand; gender was found to have an association between job demand and QoWL, where the female officers were shown to have better QoWL than their male counterparts. | Gender was considered as important in the police workforce; it was recommended that the police sector reward their workforce in order to balance the adverse effects of the demands of the job; the male workforce should be supported in order to improve their QoWL. |

WLB, work–life balance
QoWL, Quality of Working Life

3.2 Effects of work–life imbalance on women in Africa

The majority of empirical studies that have been published in Africa regarding the WLB of female employees have been mostly concentrated in Nigeria (see Table 1). This is reminiscent as the Nigerian society has been considered to be patriarchal and discriminatory against women in the workplace. This has been confirmed by the multiple research studies that have been conducted in different Nigerian organisations on women’s experiences of WLB, which yielded consistent findings and conclusions (Akanji et al. 2020; Durodulu & Mamadu 2020; Oladayo & Leah 2014; Stella et al. 2014). For instance, Akanji et al.’s (2020) study unearthed the causalities of the WLB imbalances, the stress associated with it and the adaptation strategies used by medical doctors in alleviating the impacts of such imbalances. The author traced the causes of work–life imbalance as it relates to stress, which is triggered by patriarchal attitudes in the home and disparities in salaries. Akanji et al. (2020) concluded that medical doctors in Nigeria have individual coping strategies because their organisations did not have systems and policies to assist them. Meanwhile, the (married) women who dominate the banking sector in Nigeria faced the negative effects of working long hours, which created an imbalance in their work and home activities. These authors mention that the demands of work led to them to focussing on their careers their careers and spending less time with their families. However, Stella et al. (2014) dissected WLB policies and practices in different sectors in Nigeria (including the financial sector), where policies were found to have been initiated although there were problems at the implementation stage. The authors found that different sectors have conflicting views on their understanding of WLB policies and practices and suggested that such initiatives should be incorporated into the organisational strategic plan in order to improve efficiencies and effectiveness. It was clear from Stella et al.’s (2014) findings that WLB programmes were unknown; it was recommended that such programmes be adopted in order to reduce the turnover of female staff. Women’s work–life imbalance is not only experienced in the banking sector, however; Durudulu and Mamadu (2020) mention that the female members of the Dike Library experienced adverse WLB, which had a detrimental influence on their marriages as well as work-related functions. The authors cited the toxic culture of discrimination against women in the library division, which negatively affected their productivity and upward mobility as compared to their male counterparts.

The synthesised literature above reveals the highest number of articles (8) published on WLB among Nigerian organisations. These studies paint a bleak picture of how women employees are ill-treated by pro-patriarchal organisations, with limited policies and practices to enhance a balance between their work and personal life. The studies suggest that the unfavourable conditions female employees have to work under in these organisations have destroyed their career paths, family structures and relationships. However, the published studies on WLB in Africa do not provide practical solutions, for instance, in terms of government’s legislation to deal with such a crisis in highly patriarchal countries. Furthermore, the studies are silent on the responsiveness and increase in ineffectiveness, efficiencies and productivity for those organisations that have enacted WLB policies and programmes. Also, the studies have failed to clearly show the adverse impacts of work–life imbalance on women’s psychological well-being in addition to their QoWL and QoL.

3.3 Effects of work–life imbalance on productivity

An imbalance between work and life of women in the academic sector has been observed among staff members in different African countries including Ghana, South Africa and Nigeria (see Table 1). A host of researchers (Akuamoh-Boateng 2020; Jackson & Fransman 2020; Ogunsanya & Olorunfemi 2012) have associated a work–life imbalance among female employees in universities with lower productivity. For instance, in Ghana, Akuamoah-Boateng (2020), in a study examining how women balance work and family, found that the unreasonable work schedule with often long working hours, the lack of flexible hours and the absence of policies and programmes to assist women with balancing work and life activities have adversely affected them during performance measurement periods. Another interesting empirical study by Ogunsanya and Olorufemi (2012), ascertaining an association between organisational pressures on women’s QoWL in Lagos (Nigeria), found that women work longer hours in universities, are marginalised in decision-making processes regarding their well-being and have inadequate access to healthcare facilities, which has directly hampered their productivity. Another fascinating study by Jackson and Fransman (2018), with a sample size of 252 (women) in one of the universities in South Africa, determined a correlation between female employees’ financial well-being, flexi-work and productivity. The authors revealed that financial well-being and WLB equate to women’s satisfaction at work; and that an increase in salary improves their WLB and productivity.

The reviewed but scant literature espouses how the imbalance on the relationship between women’s work and their personal lives in different sectors, including universities, has paralysed their productivity levels, putting them at a disadvantage during performance measurement sessions. However, the extent of lower productivity levels, which are the result of work–life imbalance, has not been measured empirically by scholars in the discipline.

3.4 Effects of work–life imbalance on businesses

The African women who are self-employed (entrepreneurs) also struggle to balance work and their personal lives (see Table 1). There are few inductive theory generation studies (Adom et al. 2018; Gudeta & Van Engen 2018) that have focused their research on unearthing the predicaments faced by female entrepreneurs in balancing their work and home life. In Ghana, for instance, Adom et al. (2018) purposively targeted female entrepreneurs to determine how their WLB influences their business performance. The sampled 25 women felt that their family responsibilities had a negative effect on the income generated and indicated that they have their businesses in their homes as a coping strategy. In Ethiopia, a total of 31 female entrepreneurs were selected in a study examining the challenges they face in balancing work–life responsibilities (Gudeta & Van Engen 2018). The authors found that a strategy on the WLB boundary was imposed on women and that the management of staff, family responsibilities and chores were greater demands. In private organisations, Iyabode and Olayinka (2016) have investigated the role of conflict on 265 Nigerian women’s QoWL and turnover intentions. The authors observed a close association between family–work conflict and their QoWL. Iyabode and Olayinka (2016) concluded that these organisations’ failure to retain their female workforce might result in a brain drain. Meanwhile, in Nigeria the socio-cultural pressures on women in the workplace has been found to be at the centre of challenges faced by them and that institutional policies are pro-patriarchy (Nwagbara 2020). Another intriguing research study conducted with six women (Person et al. 2016), in an attempt to

understand their contribution to work in South African organisations, revealed that autonomy at work changes their identity and self-worth and they are intrinsically satisfied. The effects of QoWL have also been experienced in the police force in Nigeria, with the opposing viewpoints for both men and women. For instance, a cross-sectional survey conducted by Ogungbamila and Idemudia (2016), where 193 women and 395 men were interviewed, resulted in an interesting finding: the male workforce had a deeper understanding of their QoWL as compared to their female counterparts. Furthermore, Ugungbamilla and Olaseni (2019) targeted 529 women and 515 men to ascertain the relationship between job demand and the police force's QoWL. The research findings showed the female police workforce as having a lower QoWL compared to the men.

The systematically synthesised literature review further reveals that the women who are entrepreneurs are negatively affected by an imbalance between their work and personal life. Women are shown in the literature to have difficulties coping with both work and family demands. The empirical studies, however, shed little light on the coping or adaptation strategies that can be utilised by self-employed women to ensure they effectively and efficiently manage their family responsibilities in addition to the staff members of their business. There is also a void in the literature that concerns the sustainability of the coping strategies used by female entrepreneurs. The interesting findings in the literature is a disjuncture between the male and female workforce's understanding of QoWL, where women have been observed to have a lower QoWL compared to their male counterparts. The imbalance between work and life and women's poor QoWL have increased their attrition percentage. Researchers have failed to determine the underlying causes and the retention strategies that are distinctive to the African context, and to respond to career women in particular.

4. CONCLUSION

There are two major themes that emerged from this literature review study: that the WLB is directly affected by unreasonable demands; and discrimination against women is present in both the home and the workplace. The abnormal work demands that have adversely and significantly affected women's QOWL and the imbalance in terms of work and home includes unsustainable work, institutionalised patriarchy, remuneration inequality, the lack of policies and interventions to mitigate or eradicate the imbalance, and longer working hours. The abnormal home and societal conditions being overloaded at home, women's role as caregivers, societal responsibilities, home chores and patriarchal attitudes directed at them. Both work and family systems do not have adequate coping and adaptation mechanisms. This has led to the increase in stress levels among women, lower productivity, ineffectiveness and inefficiencies.

The reviewed literature shows that there are limited countries in Africa where the WLB among women has been investigated, with Nigeria leading, followed by Ghana. What was noteworthy in the study was the nature and causes of work-life imbalance among women – including work overload, demands, long working hours, institutionalised patriarchy, low salaries and the absence of the wellness policies and programmes – which have lowered their performance and productivity. Apart from the patriarchal society, which is prevalent in many organisations in African countries, the socio-cultural pressures, complex family duties and chores, and societal responsibilities have negatively interfered with women's work activities. The imbalance in the relationship between work and home among African women has also been observed in those

women who are self-employed (entrepreneurs), where their family responsibilities have interfered with their business. This study concludes that the ineffectiveness between work and family roles leads to high stress levels among women and compromises their careers and families.

This article is geared towards unveiling the known gaps in the existing literature in terms of the impact work-life imbalance has on women in organisations in Africa, and which has received limited interest from researchers. This study has the potential to contribute to the theory as the article identifies existing gaps in the literature by advising future researchers to explore this unexplored topical issue. It also influences organisations in Africa to implement policies for women's wellness in order to increase their productivity. The change agents and human resource practitioners are advised through this article to focus on this overlooked dimension and implement responsive interventions to improve the balance of work and home in the lives of women in Africa.

The literature reviewed clearly depicts serious limitations and a gap in research studies on the effects on policies, systems and available programmes to improve WLB among women in organisations. The literature is also scarce on the response strategies of organisations and the systems that could enable women to adapt and mitigate the impacts of the imbalance between their work and home lives. It is therefore recommended that future researchers explore how organisations can incorporate strategies to ensure there is a balance between work and home in line managers' key performance areas (KPIs). There is a dire need for future studies to investigate the extent to which WLB in organisations can improve effectiveness and efficiencies for women in Africa. The study's limitation is methodological as it samples only the targeted female workforce; future researchers should include their male counterparts.

ABSTRACT

Wearable technology has transformed the way in which users process their health and well-being, where consumers are able to use the data generated by these devices to monitor sedentary behaviour to blood-oxygen levels, advanced heart-rate data and share this information with connections by means of a smart connected device. This technology has become accepted globally, as reflected by the projected 105.3 million units to ship by 2024. However, merely 13 percent of South African households owned such devices in 2018. Fortunately, this country is noted as the next big market for both smartwatches and fitness trackers, where Generation Y consumers, those born between 1986 and 2005, have been identified as those most likely to use fitness wearables. Despite this, and compared to global studies, there is a lack of empirical research regarding wearable activity tracker adoption in South Africa. This paper serves as a point of departure in addressing this gap in the marketing literature and reports on the validation of a model of wearable activity-tracker usage intentions amongst Generation Y students. This study collected data from 462 voluntary university students enrolled at three different public higher education institutions using a self-administered questionnaire. The measurement instrument comprised the latent factors of perceived ease of use, perceived usefulness, subjective norms, attitude and usage intentions to construct and validate a model. Data analysis procedures were performed using SPSS and AMOS version 27.0 and included reliability, validity and CFA analyses. This resulted in a validated five-factor model that can be used to measure Generation Y students' wearable activity-tracker usage intentions. This model provides marketing professionals and wearable technology device brands with a departure point for understanding Generation Y students' activity-tracker usage intentions.

Keywords: Consumer attitudes, Generation Y students, model validation, theory of reasoned action, technology acceptance model, usage intention, wearable activity trackers, South Africa

1. INTRODUCTION

The wearables industry has been thriving since 2009, especially the wearable activity tracker (WAT) market, which includes products such as basic to advanced pedometers; wrist-based fitness watches and bands; smartwatches, smart clothing like vests, socks, insoles and shoes; smart jewellery including heart-rate capable rings; smart headphones; and heart-rate-based chest, head and arm straps (Muller, 2019). With the exclusion of the smartwatch as a market on its own, the wearable activity tracker market accounted for the largest wearables category by unit sales with a projected sales income of US\$48.2 billion by 2023 (P&S Market Research, 2018). Revenue generated in 2021 is estimated at US\$134 million for the WAT market specifically (Statista, 2021). The global success of this market can partly be attributed to the vast number of benefits they offer including tracking basic health-related metrics such as heart-rate data, steps taken, calories burnt, to more advanced information like sleep patterns and quality, various sports activities including

walking, running, cycling and swimming. Since recognising that wearable fitness technology has successfully diffused throughout many consumer segments, especially in developed nations comprising the United States, Spain, Singapore and Switzerland (Ipsos, 2018), most wearable tracker brands are attempting to add as many features as possible to their entry-level up to flagship devices to remain competitive and provide value for money to their users. This approach entails adding more sensors including a combination or limitation to GPS (Glonass and/or Galileo), optical heart rate, barometric altimeter, compass, thermometer, gyroscope, and pulse oximeters to measure blood oxygen saturation, with flagship devices having an integrated solar panel. The competitive advantage, however, lies with not only manufacturing well-specified devices, but rather what they offer in addition to the technology, for example, the statistics generated by the sensors and simplifying its presentation in an application for the user to interpret without difficulty. Some brands also differentiate their position in the market by offering a digital reward system such as badges and achievements that reward users for reaching goals and foster user-communities on social media sites.

Considering the global distribution, South Africa does not share the same level of success, presenting as a nation with between 13 and 21 percent ownership of wearable technology, compared to the upper limit of more than 37 percent in other countries (Ipsos, 2018). Furthermore, data from Statista (2020) shows a wearable fitness tracker penetration rate of 7.24 percent among South Africans in 2020, with a projected decline to 6.04 percent by 2024, which can be attributed to financial and accessibility constraints due to the global pandemic. Despite this prediction, South Africa ranked 18th in terms of worldwide revenue generated and 17th in terms of user penetration in 2020 (Statista, 2020). Therefore, it is sensible to label South Africa among the top five marketers, along with Jordan, Kuwait, Indonesia and Egypt, with the greatest sales potential for wearable activity trackers (Ipsos, 2018). While being considered an emerging market for wearable fitness devices, research regarding WAT adoption behaviour in South Africa is limited.

Data show that the majority (32%) of new users of wearable technology are aged between 25 to 34 years (Ericsson Consumerlab, 2016). Statista's (2020) data show that the South African WAT segment is driven by individuals aged between 18 and 34 years. The adult portion of these consumers, born between 1986 and 2005, belong to the Generation Y cohort (Markert, 2004). Members of the Generation Y cohort have been accredited as being innovative, technologically astute and usually those who adopt new technology sooner than other generations. The student portion of this cohort was subsequently the focus of this study since these individuals, pursuing tertiary education, are regarded as future trendsetters and most likely to be employed with disposable income to spend on new technology (Bevan-Dye & Surujlal, 2011). Therefore, wearable activity tracker brands, marketing practitioners, academics and resellers can benefit from having access to a model that can be used to understand Generation Y students' WAT device usage intentions. This will enable these stakeholders to design more appropriate and targeted marketing communication and extend this foundational model in other developing nations.

To this end, this study validates a model of Generation Y students' wearable activity tracking device usage intentions in the South African context by combining two renowned models, namely the theory of reasoned action and the technology acceptance model.

2. THEORETICAL FRAMEWORK

2.1 Theory of reasoned action (TRA)

This study combined the theory of reasoned action (TRA) model and technology acceptance model (TAM) to validate a unified model of Generation Y students' wearable activity-tracker usage intentions.

The TRA, developed by Fishbein and Ajzen (1975), is one of the earliest theories to explain the adoption of technology by means of specific influencing factors, namely attitude, subjective norms and behavioural intention. The model is depicted in Figure 1.

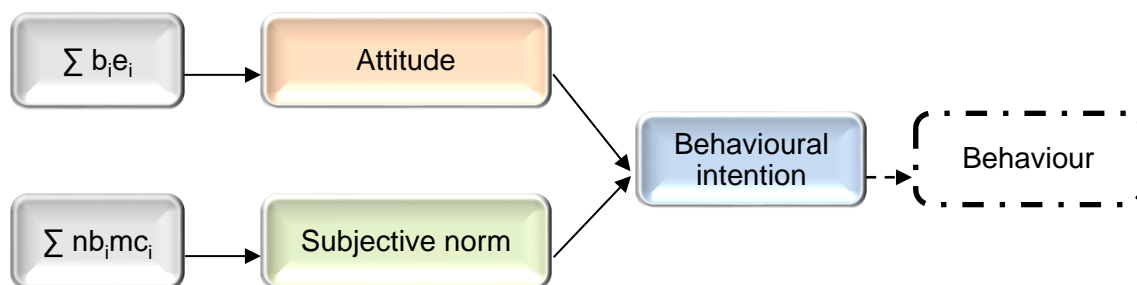

Figure 1: Theory of reasoned action (TRA) Reconstructed from Taylor & Todd, 1995:138.

When integrated with the focus of this study, wearable activity tracker purchase and usage behaviour is reflected by the behaviour component, which is theorised to be driven by behavioural intention, namely consumers' intention to use a device in the near future. This behavioural intention to use a WAT is directed by the sum of their attitudes towards wearable activity trackers and the influence of subjective norms in relation to whether relevant others think they should use these devices (Fishbein & Ajzen, 1975). First, attitudes are formed by means of the consumer's beliefs and evaluations ($\sum b_i e_i$) (Davis *et al.*, 1989:984; Taylor & Todd, 1995:138), where beliefs (b_i) are defined as "the individual's subjective probability that performing the target behaviour will result in consequence (i)" and evaluations (e_i) as "an implicit evaluative response to the consequence (i)" (Fishbein & Ajzen 1975:29). Next, subjective norms are the sum of normative beliefs and motivation to comply ($\sum nb_i mc_i$) and described as social pressures to perform a particular behaviour (Fishbein & Ajzen, 1975). That is, subjective norms are directed by consumers' normative beliefs (nb_i), which stem from the consumers' perceived expectations of specific reference groups or individuals, including peers, colleagues, friends and family and their subsequent motivation to comply (mc_i) to these expectations (Fishbein & Ajzen, 1975). Ultimately, this model suggests that a positive attitude towards WAT devices and subjective norms in favour of using these devices ought to lead to a positive intention to use the devices and, in due course, actual usage.

The TRA was deemed a suitable model to use in this study given the successful use of this model to investigate similar wearable technologies (Lin *et al.*, 2020; Hsiao & Chen, 2018)

2.2 Technology acceptance model (TAM)

While the TRA is applicable to virtually any human behaviour across different situations (Ajzen & Fishbein 1980), it does not consider perception of technology usefulness and ease of use, which is important considering that WATs are still relatively new to most South African consumers. Therefore, this study integrated the TAM to combine with the TRA into a unified, five-factor model. Davis (1986) introduced the notion that two separate salient internal belief systems, namely perceived usefulness (PU) and perceived ease of use (PEOU) have a significant influence on consumers' attitude and behavioural intention towards the acquisition and usage of new technologies (Davis, 1989). This model is shown in Figure 2.

Figure 2: Technology acceptance model (TAM) Reconstructed from Davis *et al.*, 1989:985.

When integrated with the focus of this study, wearable activity tracker purchase and usage behaviour is likewise reflected by the behaviour component, which is theorised to be driven by behavioural intention, namely consumers' intention to use a device in the near future. In accordance with the TRA, this behavioural intention to use a wearable activity tracker is directed by their attitude towards WAT devices. The TAM, alternatively, suggests that consumers' attitude towards WAT devices are, in turn, determined by the perceived usefulness and perceived ease of use of the technology, where perceived ease of use has a direct influence on the degree of perceived usefulness, which, in turn, can directly lead to behavioural intentions. In essence, if wearable activity tracking devices are perceived as being easy to use and generate useful metrics, then consumers ought to have a positive attitude towards and subsequent usage intention and, ultimately, purchase such a device.

The TAM was deemed a suitable model to use in this study given the successful use of this model to investigate relevant technologies (Felea *et al.*, 2021; Cheung *et al.*, 2020; Azharshaheen *et al.*, 2020; Lunney *et al.*, 2016; Choi & Kim, 2016; Kim & Shin, 2015).

The TRA and TAM were combined to validate whether these models can be used to measure Generation Y students' wearable activity tracker usage intentions.

3. METHODOLOGY

A descriptive research design with a single cross-sectional sampling approach guided this study

3.1 Sampling and data collection

In accordance with the primary objective of this study, the target population was defined as Generation Y university students aged between 18 and 24 years, registered at South African public

universities. The sampling frame was limited to the 26 publicly registered South African universities. Based on a non-probability, judgement sampling method, three of these universities were selected, which included one traditional university, one comprehensive university and one university of technology situated in the country's Gauteng province. This selection criterion ensured student representation from each of the country's categories of higher education institutions.

Data collection comprised following a mall-intercept type approach and 600 self-administered surveys were distributed to a non-probability convenience sample on the three campuses (200 per campus).

3.2 Research instrument

The self-administered survey included: A cover letter that explained the nature and purpose of the research and guaranteed participants anonymity; a section asking for informed consent; a section for capturing demographic data; and a section containing the scaled-response items from previously validated and published research. These scales included attitude and usage intentions as adapted from Kim and Shin (2015) and perceived ease of use as adapted from Nor and Pearson (2008). The perceived usefulness scale was retrieved and adapted from Yang *et al.* (2016) and subjective norms from the work of Lee (2009). The responses to these 18 scaled items were measured on a six-point Likert-type scale (1=strongly disagree to 6=strongly agree).

3.3 Data analysis

The gathered data were analysed using version 27.0 of IBMs Statistical Package for Social Sciences (SPSS) and Analysis- of Moment Structures (AMOS). Data analysis comprised frequencies, collinearity diagnostics, bivariate correlation analysis, validity analysis (nomological, convergent and discriminant), confirmatory factor analysis (CFA), internal consistency and composite reliability analysis.

A screening for multicollinearity issues by means of collinearity diagnostics was first performed to eliminate the possibility of excessively high correlation between the latent factors, since this would cause problems when interpreting the results of multivariate statistical analysis methods (Hair *et al.*, 2019) and cause the latent factors to not present as unique and independent. The analysis comprised of calculating the tolerance values (TV) and the variance inflation factors (VIF). Pallant (2013) indicates that TV below 0.10 and an average VIF above 10 are indicative of multicollinearity issues in the dataset. After ensuring the data adhered to these parameters, a matrix of Pearson's product-moment correlation coefficients was computed to assert the nomological validity of the data. Hair *et al.* (2019) claim that nomological validity is inferred in the presence of statistically significant relationships in the theoretically correct direction between the sets of latent factors to be included in the model. CFA was subsequently performed, using the maximum likelihood method to specify a five-factor model for testing. The first loading on each of the five latent factors was fixed at 1.0, resulting in 171 distinct sample moments and 46 distinct parameters to be estimated, equating to 125 degrees of freedom (df) based on an overestimated model and a chi-square value of 314.461, with a probability level equalling 0.000. While the chi-square statistic forms the basis for most other goodness-of-fit (GIF) indices in a model (Hair *et al.*, 2019), a statistically significant chi-square value would be indicative of poor model fit since this statistic is

sensitive to sample size and the number of observed variables (Malhotra *et al.*, 2012). As such, other model fit indices should be calculated to determine model fit. The model fit indices that were calculated to validate the model for this study consisted of the GFI, the incremental-fit index (IFI), the Tucker-Lewis index (TLI), the standardised root mean square residual (SRMR) and the root mean square error of approximation (RMSEA). According to Hair *et al.* (2019) GFI, IFI and TLI values above 0.90, together with SRMR and RMSEA values below 0.08 are indicative of acceptable model fit. Convergent validity is established with latent factor loading estimates and average variance extracted (AVE) values of 0.50 or higher, whilst discriminant validity necessitates that the square root of the AVE values exceeds the correlation estimates between the relevant latent factors and that the maximum shared variance (MSV) values are smaller than the AVE values (Hair *et al.*, 2019). Reliability was tested using Cronbach’s alpha (α) and composite reliability (CR), where values of 0.70 and above are indicative of acceptable reliability (Malhotra *et al.*, 2012). The level of statistical significance was set at $p < 0.01$ throughout.

4. RESULTS AND DISCUSSION

There was a 77 percent response rate after 462 out of the 480 returned and 600 distributed questionnaires were suitable for analysis following a Mahalanobis distance test to assess the data for multivariate outliers (Tabachnick & Fidell, 2013). There were more females (59.7%) than males (39.8%) in the sample and most were black African students between the ages of 18 and 21 years. Although the sampling was limited to Gauteng campuses, undergraduates from all but one province, Northern Cape, were represented by the sample. The proportion of responses from the traditional university and the university of technology was at the same level, whereas that from the comprehensive university was lower.

The measurement model proposed in this study was that Generation Y students’ wearable activity tracker adoption intention is a five-factor model consisting of perceived usefulness, perceived ease of use, subjective norms, attitude and wearable activity tracker adoption intention. Before constructing and testing this measurement model, a matrix of Pearson’s product-moment correlation coefficients was first constructed to test the nomological validity of the data. Following this, conventional to multivariate statistical analysis, collinearity diagnostics, which include calculating the tolerance values (TV) and variance inflation factor (VIF), was performed, thereby confirming that the model and latent factors are free of multicollinearity issues. The resulting bivariate correlation analysis and collinearity diagnostics are reported in Table 1.

Table 1: Bivariate correlation analysis and collinearity diagnostic results

| Latent factors | PU | PEOU | SN | ATT | TV | VIF |
|------------------------------|---------------|--------|--------|---------------|-------|-------|
| Perceived usefulness (PU) | | | | | 0.618 | 1.618 |
| Perceived ease of use (PEOU) | 0.322* | | | | 0.836 | 1.196 |
| Subjective norms (SN) | 0.364* | 0.153* | | | 0.839 | 1.192 |
| Attitude (ATT) | 0.523* | 0.363* | 0.283* | | 0.599 | 1.671 |
| Usage intention (UI) | 0.467* | 0.148* | 0.309* | 0.500* | 0.673 | 1.486 |

*Significant at $p < 0.01$

It is evident from Table 1 that there are statistically significant relationships ($p < 0.01$) between each of the pairs of latent factors in the correct direction, thereby indicating the nomological validity of the factors specified for inclusion in the measurement model. Furthermore, there are no multicollinearity issues since the tolerance values range from 0.599 to 0.836 and the VIF values average 1.432. The next step was to perform a CFA of the measurement model as part of validating

that the TRA and TAM can be combined to measure Generation Y students' wearable activity tracker usage intentions. This model was generated using AMOS, specifically the maximum likelihood method. Table 2 reports the correlations between the latent factors.

Table 2: Correlations between the latent factors in the measurement model

| Latent factors | Estimate |
|-----------------|--------------|
| UI ↔ ATT | 0.575 |
| UI ↔ PU | 0.511 |
| UI ↔ PEOU | 0.175 |
| UI ↔ SN | 0.330 |
| ATT ↔ PU | 0.602 |
| ATT ↔ PEOU | 0.442 |
| ATT ↔ SN | 0.304 |
| PU ↔ PEOU | 0.385 |
| PU ↔ SN | 0.378 |
| PEOU ↔ SN | 0.192 |

Similar to Table 1, it is evident that the strongest relationships were recorded between attitude and perceived usefulness and attitude and usage intentions, meaning that if Generation Y students perceive wearable activity trackers as useful, their attitudes towards these devices strengthen. Similarly, the stronger Generation Y students' attitudes towards WAT devices, the more likely they are to use them. Generation Y students' wearable activity tracker usage intentions also strongly relate to the perceived usefulness of the device and also whether their reference groups think they should use them. Perceived ease of use had the weakest relation to usage intentions, perhaps because of their tech-savvy nature, Generation Y students believe any technology is easy to use and, therefore, not such an important factor that would lead to usage intentions, as with the other factors in the model. There was also a weak relationship between subjective norms and perceived ease of use. This suggests that even if Generation Y students believe their relevant others want them to use WAT devices, this belief has no relation to whether WAT devices are easy to use.

Table 3 reports the estimates for this measurement model, including the latent factor items, the standardised loading estimates, the error variance estimates, the Cronbach alpha (α) values per factor, composite reliability CR values, the AVE and the square root of AVE values.

The Cronbach alpha value for the five-factor, 18-item model was 0.893 and with the alpha and CR values for each of the latent factors exceeding 0.70 ($p < 0.01$), it indicates the model's internal consistency and composite reliability. All the standardised loading estimates and AVE values exceed 0.50, which indicates the model's convergent validity. The model's discriminant validity is evident in that the square root of AVE for each of the latent factors exceeds its corresponding correlation coefficients and the maximum shared variance for each latent factor is smaller than its respective AVE value. With the reliability and validity of the measurement model established, the fit indices should be interpreted. The execution of the model resulted in indices indicative of acceptable model fit with a GFI of 0.924, an IFI of 0.962, a TLI of 0.953, a SRMR of 0.0435 and a RMSEA of 0.057.

Table 3: Estimates for the measurement model

| Latent factors & items | Source | Standardised loading estimates | Error variance estimates | α | CR | MSV | AVE | \sqrt{AVE} |
|--|--|--------------------------------|--------------------------|--------------|--------------|-------------|-------------|--------------|
| Perceived usefulness (PU) | Yang <i>et al.</i> (2016), as adapted from Davis (1989) | | | 0.848 | 0.852 | 0.36 | 0.54 | 0.73 |
| “An activity-tracking device is useful to your life in general.” | | 0.617 | 0.381 | | | | | |
| “An activity-tracking device provides you with useful information about your physical activity.” | | 0.721 | 0.519 | | | | | |
| “An activity-tracking device improves the quality of your physical activity.” | | 0.827 | 0.685 | | | | | |
| “An activity-tracking device increases your level of physical activity.” | | 0.746 | 0.556 | | | | | |
| “An activity-tracking device enhances the effectiveness of your physical activity.” | | 0.737 | 0.543 | | | | | |
| Perceived ease of use (PEOU) | Nor & Pearson (2008) | | | 0.755 | 0.762 | 0.20 | 0.52 | 0.72 |
| “Learning how to use an activity-tracking device is easy.” | | 0.638 | 0.408 | | | | | |
| “It is easy to use an activity-tracking device to track your daily activity.” | | 0.827 | 0.684 | | | | | |
| “It is easy to remember how to use an activity-tracking device.” | | 0.684 | 0.468 | | | | | |
| Subjective norms (SN) | Lee (2009) as adapted from Wu and Chen (2005) | | | 0.946 | 0.947 | 0.14 | 0.86 | 0.93 |
| “People who are important to me think I should use an activity-tracking device.” | | 0.914 | 0.835 | | | | | |
| “People whose opinions I value think I should use an activity-tracking device.” | | 0.964 | 0.929 | | | | | |
| “People who influence my decisions think that I should use an activity-tracking device.” | | 0.896 | 0.802 | | | | | |
| Attitude (ATT) | Kim and Shin (2015) as adapted from Venkatesh <i>et al.</i> (2003) | | | 0.828 | 0.832 | 0.36 | 0.56 | 0.75 |
| “Using an activity-tracking device is a good idea.” | | 0.700 | 0.491 | | | | | |
| “Generally, I have a favourable attitude towards using an activity-tracking device.” | | 0.649 | 0.421 | | | | | |
| “I like the idea of using an activity-tracking device.” | | 0.831 | 0.690 | | | | | |
| “Overall, I think using an activity-tracking device is beneficial.” | | 0.786 | 0.618 | | | | | |
| Usage intention (UI) | Kim and Shin (2015) as adapted from Venkatesh <i>et al.</i> (2003) | | | 0.919 | 0.920 | 0.33 | 0.79 | 0.89 |
| “I intend to use an activity-tracking device in the future.” | | 0.875 | 0.766 | | | | | |
| “I predict I will use an activity-tracking device in the future.” | | 0.911 | 0.830 | | | | | |
| “I plan to use an activity-tracking device in the future.” | | 0.884 | 0.781 | | | | | |

With all the indices' values considered, this suggests that Generation Y students' wearable activity tracker usage intentions is a five-factor model, presented in Figure 3, that exhibits construct validity, reliability and acceptable model fit. The measurement model depicted in Figure 3 shows the standardised model.

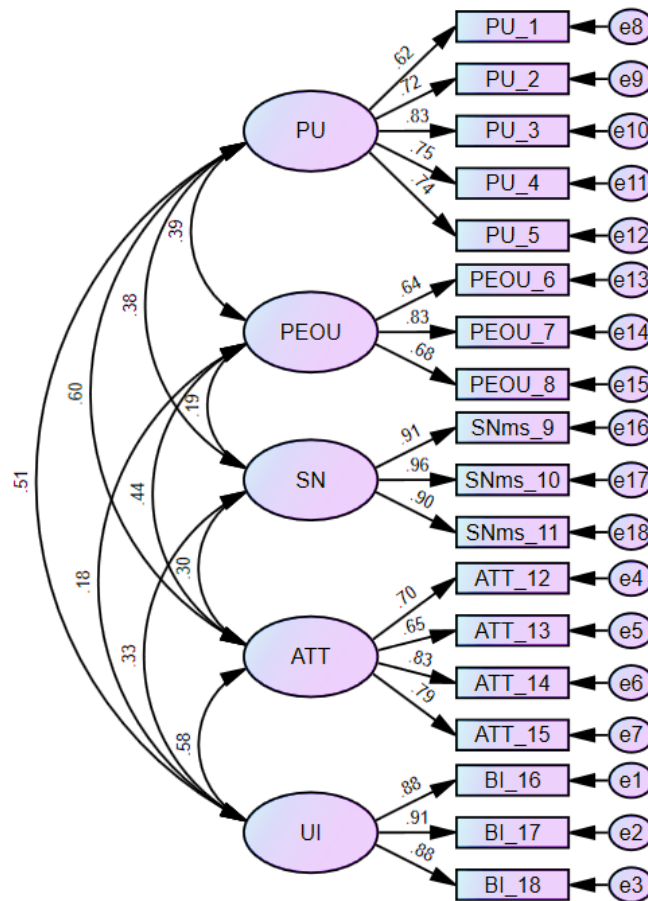

Figure 3: Validated model of Generation Y students' wearable activity tracker usage intentions

5. CONCLUSION

The purpose of this study was to validate a model of Generation Y students' wearable activity-tracking device usage intentions in the South African context. Given the growth of the wearables market, specifically that of wearable activity trackers among Generation Y consumers, it is vital that marketers have a model to measure and understand their usage intentions of these devices. The results of this study suggest that the TRA and TAM can be combined into a five-factor model consisting of perceived usefulness, perceived ease of use, subjective norms, attitude and usage intentions in the context of measuring WAT adoption behaviour. The measurement model tested showed no multicollinearity issues, construct validity relating to nomological, convergent and discriminant validity, both internal consistency and composite reliability and acceptable model fit.

All the factors had a significant relation to Generation Y students' wearable activity trackers usage intentions, with attitude having the strongest and perceived ease of use the weakest relation to their usage intentions. However, it is vital to conduct path analyses for all the latent factors to isolate the exact influence the factors have on usage intentions to make more accurate predictions of wearable activity tracking device adoption behaviour.

Hence, from a practical perspective, this model can be used as a foundation for wearable activity tracker device manufacturers or brands, marketing practitioners and academics to investigate Generation Y consumers' wearable activity tracker device usage intentions. Knowing this cohort's usage intentions would be useful to grow the wearable market in the country and perhaps, internationally.

For this model to be implemented to predict behaviour based on the factors in the model, future research is needed and should focus on the paths and influence of perceived usefulness, perceived ease of use, subjective norms and attitude on usage intentions, which would ultimately forecast actual behaviour. Once the effect of these variables is investigated, brands and marketing practitioners can integrate relevant strategies to attract a larger consumer base and also develop appropriate marketing communication that aligns with these factors.

APPLICATION OF JUST-IN-TIME APPROACH AT A SELECTED TELECOMMUNICATION CORPORATION

S. Govuzela

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

Materials and operations managers within the Materials Management section of Telkom South Africa in Gauteng Province were of the view that the company is losing considerable money due to inventory costs. Inventories were ordered in bulk, which resulted in some inventories becoming obsolete before being used. Inventories amounting to millions of Rand were also lost and some became defective. This study was prompted by the inventory cost challenges experienced by the Materials Management section of Telkom South Africa in Gauteng Province. Using a quantitative approach and cross-sectional survey research design, a self-administered survey questionnaire was emailed to 60 selected employees. Descriptive statistics were employed to analyse data about the profiles of participating respondents. Results of the study showed that staff were aware of the inventory costs incurred and were aware that the JIT approach is the technique that can eliminate these inventory costs. Staff were optimistic that the JIT approach is the technique that can improve financial performance and materials delivery. Staff also indicated that the JIT approach is the technique that can eliminate materials problems. Staff perceived the JIT approach as the technique that can improve service delivery and overall performance. Results also revealed that the Materials Management section of Telkom South Africa in Gauteng Province did not use the JIT approach in ordering materials and, therefore, incurred unnecessary inventory costs. In view of the study results, it is recommended that the Materials Management section of Telkom South Africa in Gauteng Province adopt the JIT philosophy. By doing so, it will benefit by eliminating unnecessary inventory costs. It is also recommended that the Materials Management section of Telkom South Africa in Gauteng Province should work on implementing the JIT approach to enhance its inventory levels. It is further recommended that this study be conducted in other state-owned enterprises as well.

Keywords: Materials, Inventory, Just-in-time, Inventory costs, Materials Management

1. INTRODUCTION

Telkom South Africa is a leading information and communications technology (ICT) service provider in South Africa. Its offering includes fixed-line, mobile and data services and information technology (IT) services. Telkom South Africa is listed on the Johannesburg Stock Exchange (JSE). The South African government owns 40.5 percent of Telkom South Africa and 51.6 percent of the shares are held by institutional shareholders (Telkom South Africa, 2020). Telkom South Africa's purpose is to connect its customers to a better life seamlessly (Telkom South Africa, 2020).

Materials and operations managers within the Materials Management section of Telkom South Africa in Gauteng Province were of the view that the company is losing considerable money due to inventory costs. Inventories were ordered in bulk, which resulted in some inventories becoming

obsolete before being used. Inventories amounting to millions of Rand were also lost and some became defective. This study was prompted by the inventory cost challenges experienced by the Materials Management section of Telkom South Africa in Gauteng Province.

These inventory cost challenges resulted in the company retrenching some employees and some were forced to take early retirement. Some sections within the Materials Management section of the Telkom South Africa in Gauteng Province were forced to shut down due to these financial losses.

Materials and operations managers within the Materials Management section of Telkom South Africa in Gauteng Province did not use the just-in-time (JIT) approach to order materials. As a result, the Materials Management section of Telkom South Africa in Gauteng Province incurred unnecessary inventory costs, which resulted in the above financial challenges. This study is of paramount importance as there are no previous studies conducted in this specific subject field.

2. PURPOSE OF THE STUDY

The purpose of the study was to explore the extent to which the Materials Management section of Telkom South Africa in Gauteng Province applies the JIT approach in order to eliminate waste and avoid unnecessary inventory costs.

3. PROBLEM INVESTIGATED

The application of JIT approach within the Materials Management section of Telkom South Africa in Gauteng Province was investigated, as well as the unnecessary inventory costs incurred.

4. RESEARCH OBJECTIVES

The following theoretical objectives were formulated:

- (i) To provide a theoretical overview of various inventory costs.
- (ii) To carry out a literature study on the importance of the JIT approach.

The theoretical objectives were supported by the following empirical objectives:

- (i) To identify problems associated with materials handling at the Materials Management section of Telkom South Africa in Gauteng Province.
- (ii) To highlight areas that operations managers can focus on as priorities to improve materials management at Telkom South Africa in Gauteng Province.
- (iii) To demonstrate how the Materials Management section of Telkom South Africa in Gauteng Province can embrace the JIT approach as a philosophy with a view to improving materials management.

5. LIRETATURE REVIEW

5.1 Just-In-Time (JIT) Approach Philosophy

Although precisely defining the JIT approach continues to be perplexing, the JIT approach is generally referred to as a manufacturing system for achieving excellence through continuous quality improvements. With regards to productivity, rework of manufactured products and waste has a direct impact on the profits of a company (Van Wyk & Naidoo, 2016). According to Mankazana and Mukwakungu (2018), the JIT approach is a materials management approach of

delivering the exact amounts of materials, at the exact times, when needed. According to a study undertaken between 1981 and 2000 in the US, it was found that manufacturing companies with less materials in the warehouse are more efficient than those with more materials in the warehouse. Thus, it was found that an organisation that keeps moderate materials in the warehouse can successfully eliminate unnecessary inventory costs.

Franco and Rubha (2017) indicate that the JIT approach is both a philosophy and set of methods for manufacturing. According to this concept, materials are supplied to the workstation just at the time that they are required for use. Mukwakungu, Mabasa, Mankazana, Mzileni and Burakeye (2019) state that JIT approach is a philosophy that relates to the manufacturing industry, which plans to dispose of waste, as waste is or results from any action that adds cost to the process of production without essentially increasing the value of the item being produced.

5.1.1 Objectives and Advantages of JIT Approach

According to Mankazana and Mukwakungu (2018), the objectives of JIT approach are to deliver the goods at the right time for them to be sold, to deliver the sub-assemblies at the right time for them to be turned into a finished product, to deliver the fabricated parts at the right time for them to be turned into sub-assemblies and to deliver purchased materials at the right time, at the right place. Mankazana and Mukwakungu (2018) indicate that JIT approach result in the reduced amount of space that the company will need. That space which is now available can be utilised for other profitable business activities. A faster dispatch of inventory by employing JIT approach prevents the material becoming damaged and turning into waste. This again decreases costs by preventing investment in unnecessary stock and reducing the need to replace unused damaged stock. The JIT approach helps companies not to make major investments in materials, as materials will only be ordered and delivered when needed.

5.2 The Concept of Materials Management

Materials management is defined as a set of predetermined activities of an institution, which consist of planning, sourcing, purchasing, transporting, storing, utilising, controlling and disposal or recycling of materials in an optimum manner, with the aim to provide quality care with affordable costs to the customers without any interruption of service (Kaur, 2016). According to Jobin (2019), management of necessary materials without wasting money, time and effort is of vital importance in society, as the world faces a shortage of resources today.

Materials management is related to planning, procuring, storing and providing the appropriate material of right quality, right quantity at the right place and at the right time (Kaur, 2016). Proper materials management prevents the wastage of time, plays a vital role in increasing the profit of the organisation, ensures the quality of materials, increases productivity of the employees and minimises waste (Jobin, 2019).

6. RESEARCH METHODOLOGY

6.1 Study Design

A quantitative approach and cross-sectional survey research design was used in this study. This involved the administration of a self-administered survey questionnaire to the sample at just one point in time, which provides a snapshot of what was happening in that group at that particular

time (Saunders, Lewis & Thornhill, 2016). The study used a quantitative research approach because it intended to produce comparable results that can be generalised to the telecommunications industry in other environments apart from Gauteng Province

6.2 Study Population and Sampling Strategy

For this study, Telkom South Africa Materials Management, Access Turf Management, Inventory Management and Contract Management sections within Gauteng Province were the study population. The size of this study population was 600 employees. These comprised project administrators, Project Coordinators, Operations Project Managers, Operations Managers, Senior Contract Representatives and Managers from the designated areas.

Purposive sampling was used in this study. According to Etikan, Musa and Alkassim (2016), the purposive sampling technique, also called judgmental sampling, is the deliberate choice of a participant due to the qualities the participant possesses. It is a non-random technique that does not need underlying theories or a set number of participants. Simply put, the researcher decides what needs to be known and sets out to find people who can and are willing to provide the information by virtue of knowledge or experience. Purposive sampling techniques was appropriate for this study because researcher deliberately chose the participant due to the qualities they possess.

A sampling frame is a list of the actual cases from which sample will be drawn. The sampling frame must be representative of the population (Taherdoost, 2016). The sampling frame for this study was the list of all employees at Telkom South Africa Materials Management, Access Turf Management, Inventory Management and Contract Management sections within Gauteng Province.

A sample size that is too small could lower the sensitivity of the experiment to identify significant differences; whereas a sample that is too large could waste time, cost and resources or important investigational endpoint. In the latter case, a trade-off may often occur between the cost-effectiveness and detecting power. As such, it is difficult to determine the sample size for studies, especially in confirmatory studies (Ko & Lim, 2021). Based on these, the sample size for this study, which was randomly selected respondents, was $n=60$. The sample size used is in line with similar studies conducted by Lekhanya (2016).

6.3 Data Collection

Self-administered survey questionnaires are an important data collection tool in clinical practice, public health research and epidemiology. They are ideal for achieving a wide geographic coverage of the target population, dealing with sensitive topics and are less resource intensive than other data collection methods. These survey questionnaires can be delivered electronically, which can maximise the scalability and speed of data collection while reducing cost (Belisario, Jamsek, Huckvale, O'Donoghue, Morrison & Car, 2015).

A self-administered survey questionnaire was used to collect data from the sample. For the purpose of this study, great care was undertaken in the development of the self-administered survey questionnaire, to ensure that questions were clear, simple and unambiguous. Reliability and validity were applied to ensure the accuracy of measurement scales.

Reliability refers to the consistency of test results (Akib, Najib & Ghafar, 2015). Reliability concerns the extent to which a measurement of a phenomenon provides stable and consistent results. Reliability is also concerned with repeatability. A scale or test is said to be reliable if repeat measurement made by it under constant conditions will give the same result. Testing for reliability is important as it refers to the consistency across the parts of a measuring instrument (Taherdoost, 2016).

Validity explains how well the collected data covers the actual area of investigation. Validity basically means “measure what is intended to be measured” (Taherdoost, 2016). Two types of validity were tested in this study. The first was face validity, which was ascertained through the review of the self-administered survey questionnaire by a panel consisting of academics at my university. The second type of validity tested in this study is content validity. This was ascertained through a pilot study of the self-administered survey questionnaire, using a conveniently selected sample of 10 management staff. These management staff were excluded from participating in the final survey. Feedback from the review panel was used to effect minor changes to the self-administered survey questionnaire to ensure that questions were simpler, more direct and terms used were non-technical. After analysis of the pilot study results, items that had low factor loadings were removed, and the self-administered survey questionnaire was shortened to avoid respondent boredom, which could have resulted in unanswered questions.

Self-administered survey questionnaire was e-mailed to 60 elements of the sample who were selected according to their vast experience in materials management. After a few days, the same self-administered survey questionnaire was e-mailed again to encourage a higher response rate. A follow-up was done by delivering self-administered survey questionnaires by hand to some of the individuals who did not respond. As a result, 47 self-administered survey questionnaires were received, which is a response rate of 78 percent. This response rate indicated a reliable, valid and good response rate for data analysis. According to Nguegan Nguegan and Mafini (2017), this response rate was reliable for analysis and interpretation because it is above the 50 percent minimum threshold.

Researchers need to target populations that are more likely to be interested in the study to increase the response rate for their surveys (Saleh & Bista, 2017). In this study, the employees involved in Materials Management Section of Telkom South Africa in Gauteng Province were targeted. It was assumed that they would be interested in the study results. This could be the reason that the response rate for this survey was 78 percent.

6.4 Data Analysis

The first step in analysing the collected data was to screen the self-administered survey questionnaires and eliminate the unusable ones. The following step was to code the data on a Microsoft Excel spreadsheet, followed by cleaning the data to identify and rectify missing entries. The next step was to import the data into the Statistical Package for Social Sciences (SPSS version 24). After that, descriptive statistics were employed to analyse data about the profiles of participating respondents.

6.5 Ethical Considerations

In this study, several ethical principles were considered. First, permission was obtained from participants who were employed at Telkom South Africa Materials Management, Access Turf Management, Inventory Management and Contract Management sections within Gauteng Province to conduct the survey. Secondly, respondents were under no obligation to complete the self-administered survey questionnaires. A potential respondent who refused to participate in the research was excused and the next qualifying individual was approached to participate. This ensured that respondents' rights to non-participation were observed. Thirdly, all respondents were adequately informed about the purpose of the study to secure their informed consent. Finally, anonymity and confidentiality of respondents were protected throughout the study. Anything learnt about respondents during their involvement in the study was maintained in confidence.

7. RESULTS

The following table indicates the staff's awareness of inventory costs incurred by Telkom South Africa in Gauteng Province.

Table 1: Staff's awareness of inventory costs incurred

| | Frequency | Percentage | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| Yes | 23 | 46.9 | 47.9 | 47.9 |
| No | 15 | 30.6 | 31.3 | 79.2 |
| Do not know | 10 | 20.4 | 20.8 | 100.0 |

As indicated in Table 1, 46.9 percent (n = 23) of staff were aware of the inventory costs incurred by the Materials Management section of Telkom South Africa in Gauteng Province.

Table 2: The technique that staff think can eliminate inventory costs

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 12 | 24.5 | 41.4 | 41.4 |
| MRP | 7 | 14.3 | 24.1 | 65.5 |
| Forecasting | 9 | 18.4 | 31.0 | 96.6 |
| Other | 1 | 2.0 | 3.4 | 100.0 |

Table 2 shows that 24.5 percent (n = 12) believed that the JIT approach is the technique that can eliminate these costs.

Table 3: The technique that staff think can improve financial performance

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 15 | 30.6 | 33.3 | 33.3 |
| MRP | 12 | 24.5 | 26.7 | 60.0 |
| Forecasting | 13 | 26.5 | 28.9 | 88.9 |
| Other | 5 | 10.2 | 11.1 | 100.0 |

Table 3 indicates that 30.6 percent (n = 15) were optimistic that the JIT approach is the technique that can improve financial performance within the Materials Management section of Telkom South Africa in Gauteng Province. In the abovementioned tables (tables 1–3), it is evident that the JIT approach was the most preferred technique compared to other techniques.

Table 4: The system that staff think can improve material delivery

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 11 | 22.4 | 25.0 | 25.0 |
| MRP | 13 | 26.5 | 29.5 | 54.5 |
| Forecasting | 11 | 22.4 | 25.0 | 79.5 |
| Other | 9 | 18.4 | 20.5 | 100.0 |

It is shown in Table 4 that 22.4 percent (n = 11) of staff thought that the JIT approach is the technique that can improve materials delivery.

Table 5: The technique that staff think can eliminate materials problems

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 12 | 24.5 | 27.3 | 27.3 |
| MRP | 16 | 32.7 | 36.4 | 63.6 |
| Forecasting | 13 | 26.5 | 29.5 | 93.2 |
| Other | 3 | 6.1 | 6.8 | 100.0 |

In Table 5, 24.5 percent (n = 12) of staff indicated that the JIT approach is the technique that can eliminate materials problems.

Table 6: The technique that staff think can improve service delivery

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 13 | 26.5 | 28.3 | 28.3 |
| MRP | 14 | 28.6 | 30.4 | 58.7 |
| Forecasting | 13 | 26.5 | 28.3 | 87.0 |
| Other | 6 | 12.2 | 13.0 | 100.0 |

Table 6 shows that 26.5 percent (n = 13) of staff perceived the JIT approach as the technique that can improve service delivery within the Materials Management section of Telkom South Africa in Gauteng Province.

Table 7: The technique that staff think can improve overall performance

| | Frequency | Percent | Valid percent | Cumulative percent |
|-------------|-----------|-------------|---------------|--------------------|
| JIT | 13 | 26.5 | 29.5 | 29.5 |
| MRP | 15 | 30.6 | 34.1 | 63.6 |
| Forecasting | 11 | 22.4 | 25.0 | 88.6 |
| Other | 5 | 10.2 | 11.4 | 100.0 |

Table 7 shows the technique that staff think will improve overall performance within the Materials Management section of Telkom South Africa in Gauteng Province. Table 7 shows that 26.5 percent (n = 13) of staff indicated that the JIT approach is the system that can improve the overall performance within the materials management section of Telkom South Africa in Gauteng Province. The JIT approach was chosen less often in the abovementioned four tables (tables 4–7). Nevertheless, the overall results show that JIT approach was the most favoured technique.

Results of the study showed that staff were aware of the inventory costs incurred and were aware that the JIT approach is the technique that can eliminate these inventory costs. Staff were optimistic that the JIT approach is the technique that can improve financial performance and materials delivery. Staff also indicated that the JIT approach is the technique that can eliminate materials problems. Staff perceived the JIT approach as the technique that can improve service delivery and overall performance. Results also revealed that the Materials Management section of Telkom South Africa in Gauteng Province did not use the JIT approach in ordering materials and, therefore, incurred unnecessary inventory costs.

8. CONCLUSIONS

The study concludes that the JIT approach can contribute positively towards optimal inventory levels in the Materials Management section of Telkom South Africa in Gauteng Province. The JIT approach can assist organisations in improving overall productivity and eliminating waste. It can provide for the cost-effective production and delivery of only the necessary quantity of parts of

the right quality at the right time and place, while using the minimum amounts of facilities, equipment, materials and human resources.

9. MANAGERIAL IMPLICATIONS

In the light of the results of this study, several managerial implications may be put forward. To maintain satisfactory levels of inventory, the Materials Management section of Telkom South Africa in Gauteng Province should adopt technology-driven systems such as JIT, value analysis, concurrent engineering and modular design systems. Future technology investments should be directed to investing in upgrading production, information and inventory management systems to meet international standards.

In view of the study results, it is recommended that the Materials Management section of Telkom South Africa in Gauteng Province adopt the JIT philosophy. By doing so, it will benefit by eliminating unnecessary inventory costs. It is also recommended that the Materials Management section of Telkom South Africa in Gauteng Province should work on implementing the JIT approach to enhance its inventory levels. It is further recommended that this study be carried out in all state-owned enterprises (SOEs) as well.

FACTORS INFLUENCING GENERATION Y CONSUMERS PURCHASE BEHAVIOURS OF ORGANIC PRODUCTS

C. Synodinos

North-West University, Vanderbijlpark, South Africa

K.L. Sharp

North-West University, Vanderbijlpark, South Africa

ABSTRACT

The modern-day consumer is constantly overwhelmed by numerous environmental issues currently grasping the environment and the natural world. Global warming, deforestation, overpopulation and pollution among many other concerns are constantly highlighted, resulting in consumers altering the way they purchase their products. Not only are consumers buying products to aid in the environmental war, but they are purchasing food products that are better for their own health. Food products that have been manufactured in an organic fashion are said to be healthier than traditional food products, as organic products are made free from pesticides, hormone stimulants and processed chemicals. There are various factors that may influence a consumer to purchase an organic product. The question that begs to be asked is, are consumers purchasing organic food products more for environmental preservation, self-health reasons or the status-quo of friends and family? The primary objective of this study is to identify which factors explain the recent upsurge of organic food product purchases of the Generation Y cohort in South Africa. The sample for this study comprised 500 Generation Y consumers drawn from across South Africa. The data were collected by a specialist data collecting organisation. The target market consisted of South African citizens, ranging in age from 18 to 35 years. The collected data were analysed using descriptive statistics, Pearson's product-moment correlation coefficient, regression analysis and an independent samples t-test. The results indicate that Generation Y consumers display positive intentions towards organic food purchase behaviour. Various factors such as the physical ability to attain organic products and the perceptions of friends and family regarding the purchasing of organic food products played a significant role in the purchase thereof. The results from this study will aid both business practitioners and marketing academics in forming a better understanding of the Generation Y consumer in terms of their organic food purchase behaviours. Furthermore, this study outlines marketing strategies geared towards effective green pricing policies.

Keywords: Organic food; purchase behaviour; Generation Y; South Africa

1. INTRODUCTION

Given the increased hazardous issues that consumers face in the current environment, environmental awareness has become increasingly prevalent. Changes in the way consumers make decisions regarding food purchases have led to an increase in the attention consumers pay towards organic food products, where consumers are more inclined to consume organic products compared to traditional food products. This change in consumer consumption is ascribed to factors, including environmental issues, health concerns, future preservation and natural taste. Research shows that

these organic food choices are a result of consumers wanting to make lifestyle changes, which include being more environmentally conscious or loyal to pro-environmental causes. For the purpose of this study, Padmaja and Parashar (2018) articulate organic products as food products that have undergone minimal processing, in an effort to produce food products that maintain the integrity of food, without the use of preservatives, artificial ingredients or irradiation. Sing and Verma (2017), Watson (2017) and Paul and Rana (2012) add that organic products are developed by employing the use of environmentally friendly processes and the use of cultivation techniques, which are concerned with both the attributes of the final product being produced, as well as the production process undertaken.

Specific standards must be adhered to when producing products related to organic agriculture if organisations wish to produce products that can be classified as “organic”. These include production, processing, transport, packaging and distribution standards (Sing & Verma, 2017; Paul & Rana, 2012). In South Africa, organic farming constitutes the production of food crops and livestock in a manner that is harmonious with nature. Consequently, organisations involved in organic food production and farming need to ensure that they preserve the natural resources of South Africa as much as possible. Some of the preservation measures that can be employed are the use of soil quality improvement, water-wise crops, the humane management of livestock and the most economical ways in which to use water (South Africa Online, 2021).

According to Bhalla (2020), there has been a significant increase in the demand for organic foods across the world in recent years. With regard to organic food and environmentalism in its entirety, the demand from South African consumers for organic products and safer sustainable business practices is becoming increasingly prevalent. For businesses that wish to stay relevant in the ever-changing consumer market, it is imperative that they heed to the potential influence of this environmental movement, highlighting the importance of complying with this new demand. In comparison to traditional products, organic product prices are perceived as being more expensive, which directly influences the purchase decision of a product. As the demand for organic products increases, prices should begin to decrease, which will, in turn, encourage consumers to make more purchases. Other factors, such as subjective norms, health consciousness, attitudes and overall purchase behaviour may also influence the purchase decision of organic products. Consequently, the question then posed is, what factors influence the South African Generation Y consumer to purchase organic products.

This paper includes a literature review on subjective norms, health consciousness, attitudes towards organic food, purchase intention and actual buyer behaviour and the Generation Y cohort. Furthermore, the paper highlights the research methodology used, including the sampling and data collection methods and the research instrument employed. The results are then discussed, followed by the conclusion, including the recommendations, study limitations and future study directions.

2. LITERATURE REVIEW

Subjective norms

Subjective norms may be defined as the views of significant others that individuals use in an advisory capacity regarding how to perform or not to perform specific behaviours and motivations, in addition to a willingness to undertake or not undertake a particular task that is deemed important (Utami, Bernardus & Sintha, 2017). Conner and Armitage (1998) define significant others as

individuals whose preferences regarding a particular behaviour are held in high esteem by an individual. According to Al-Debei, Al-Lozi and Papazafeiropoulou (2013), individuals tend to behave in a way that is accepted and encouraged by the individuals they deem as significant others.

Although previous research has alluded to the fact that one of the pitfalls of the theory of planned behaviour is the significantly weak relationship that exists between subjective norms and intentions, Ajzen (1991) explains that intentions are significantly influenced by personal factors, including attitudes and perceived behavioural control. Ham, Jeger and Ivkovi (2015) propose that the confirmed correlation between descriptive norms and intentions implies the possibility of the predictive power of this variable, which provides a strong motivation for further research in this area. Descriptive norms are defined as real-life activities and behaviours that individuals are engaged in. Furthermore, social norms refer to the perception of other individuals' opinions on how an individual should behave. As such, both descriptive and social norms are combined to form the subjective norms factor (Unicef, 2021).

According to Hansen, Sørensenb and Eriksenc (2018), an individual's identity is significantly associated with social consciousness towards behavioural intention with regard to the purchasing of organic foods. Ossowski (2001) indicates that social consciousness is the term used to describe a set of common characteristics that individuals who belong to a particular social environment may possess, which is reinforced in the consciousness of particular individuals through mutual suggestion and by the conviction that these characteristics are shared by other individuals within the same group. This may lead to consumers feeling pressured into identifying as being environmentally friendly individuals who are concerned with the quality and safety of the food products they purchase and ultimately consume.

Health consciousness

According to Afable (2019), health consciousness is the term used to define an individual's cognisance of the extent to which their diet and lifestyle may be viewed as healthy. Phan and Mai (2016) add that health consciousness is the subjective intent or motivation of consumers to improve their health. Wolfson (2019) argues that organic food products are free from chemicals and are not only beneficial in their ability to enhance health through consumption, but through the simultaneous improvement of the environment. Consequently, consumers with an increased level of concern regarding food safety possess positive attitudes towards organic food products (Tandon *et al.*, 2021).

Asare-Bediako (2015) postulates that the most prevalent influencing factor of consumer behaviour associated with the purchasing of organic products is health consciousness. The health concerns of individual consumers are more widespread in the influence on organic purchases, compared to those concerning the environment and the protection of biodiversity (Xie *et al.*, 2015; Paul & Rana, 2012). Antioxidants, which are found in conventional soil, provide organic crops and foods with nutritional superiority, which become even healthier due to the absence of pesticides and chemicals. In addition, organic products tend to have lower levels of the metal, known as cadmium (Wolfson, 2019).

Attitudes towards organic food, purchase intention and actual buyer behaviour

According to the theory of planned behaviour (Ajzen, 1991), the more positive an individual's attitude towards engaging in a behaviour is, the more inclined an individual will be to engage in

that specific behaviour. As such, positive consumer attitudes towards organic food products tend to result in positive consumer attitudes towards the actual purchase of organic food products. Liang (2016) predicts that as a result, consumers become more inclined to develop an intention to purchase organic food products.

Based on the increase in consumers' health consciousness and environmental preservation, the demand for organic products has increased (Xie *et al.*, 2015; Dunn *et al.*, 2014). Therefore, consumers' concerns regarding health and environmental safety are contributing factors to consumers' buying behaviours pertaining to organic products (Bizcommunity, 2017; Xie *et al.*, 2015; Magnusson *et al.*, 2001). This has led to an alteration in the purchase patterns and purchase behaviours of consumers (Lim *et al.*, 2014).

Generation Y cohort

As of 2019, 37 percent of South Africa's population constituted Generation Y individuals who were considered ecologically aware (Statistics South Africa, 2019; Eastman & Liu, 2012). For the purpose of this study, the Generation Y cohort comprises individuals who were born between 1986 and 2005, making this cohort aged between 17 and 36 years in 2022. The individuals of the Generation Y cohort, who possess a tertiary education, are viewed as trendsetters and influencers, who are opinionated and able to secure jobs that have higher than average earning power, which has led to a significant increase in the disposable incomes of these individuals (Bevan-Dye & Surujlal, 2011). When investigating the environmental movement, it is evident that the individuals of the Generation Y cohort are the forerunners of this phenomenon (Eastman & Liu, 2012). The purchasing patterns of the individuals of the Generation Y cohort, highlight the inclination these individuals have to invest in an environmentally sustainable lifestyle (Huh & Chang, 2017; Rogers, 2013). For these individuals, supporting socially responsible organisations, which are known to give back to the community, who actively get involved with environmental conservation and who endeavour to incorporate sustainability programmes into organisational operations, is key (Huh & Chang, 2017; Smith, 2012; Thieme *et al.*, 2015). Consequently, organisations should strive to develop sustainable marketing strategies targeted towards the Generation Y cohort, while simultaneously developing a deeper understanding of the environmental Generational Y consumer, as these individuals represent both the future consumer and the future of the environmental movement (Taufique & Vaithianathan, 2018; Kanchanapibul *et al.*, 2014).

3. METHODOLOGY

3.1 Research design

The research design for this study was descriptive in nature. Moreover, the study implemented a single cross-sectional analysis. This research design entails collecting data from subjects at a single point in time, as opposed to a longitudinal study which records multiple responses of the same subjects on various occasions (Shukla, 2010:38).

3.2 Target population

The target population for this was the South African Generation Y consumer aged between 18 and 35 years. The components of the target population are as follows:

- Element: South African consumers

- Sampling unit: Market research panel
- Extent: South Africa
- Period: 2021

3.3 Sampling technique and data collection

To gather the required data for this study, a convenience sampling technique was carried out. The researchers made use of an internationally renowned market research company to acquire the data. The marketing research company has a panellist data set consisting of roughly 40 000 participants from across Southern Africa. As the research company has such a vast pool of respondents, the response rate is then normally 100% of the sample size. The age parameters were set to the range between 18 and 35 over a three-day collection time period.

3.4 Sample size

The sample size for this study was based on previous studies similar in nature. As such, the sample size of 500 participants was deemed as viable for the purpose of this study. Previous studies include: Hansmann *et al.* (2020:1) (sample size: 620); Wang *et al.* (2020:1) (sample size: 518); Liang (2016:183) (sample size: 507) and Yin *et al.* (2010:1361) (sample size: 432).

3.5 Measuring instrument and data collection technique

The research company IPOS made use of their FastFacts method to collect the data for this study. The FastFacts program requires participants to undertake a structured self-administered online questionnaire. The measuring instrument was adapted from various published and validated research. The questionnaire was split into two sections namely Section A, which included all relevant demographical data and Section B, which measured the factors influencing Generation Y consumers' intentions to purchase organic products. To determine Generation Y consumers' level of subjective norms, the validated scale of Fielding *et al.* (2008) was used, while, health consciousness was taken from the study of Tarkianen and Sundqvist (2005). Generation Y consumers' purchase intentions and purchase behaviours were measured using the adapted validated scales from Mostafa (2007) and Lee (2008), respectively. A Likert scale based on a six-point range was the chosen tool for capturing the responses of participants, where the scale ranged from strongly disagree (1) to strongly agree (6). Before respondents answered any questions they were shown a cover letter, which explained the purpose of the study, which provided all relevant contact information of the researchers and also assured participants that their information would remain anonymous and all data would only be used in a statistical nature.

The FastFacts questionnaire program ensures that participants cannot move from one section of the questionnaire to the next before completing every item in the section they are busy with. The time frame for the questionnaire was twofold, first the availability of the questionnaire was set at a maximum of three days and second the questionnaire would no longer be available if 500 responses were reached before the time limit had expired. This study reached the 500 target well before the three-day time limit. As such, the response rate was then 100 percent.

4. RESULTS AND DISCUSSION

IBM SPSS Statistics 27 was used to identify and analyse the captured data. Various statistical techniques were employed to achieve the objectives of the study. The statistical techniques included outlier statistics, internal-consistency reliability, descriptive statistics, correlation analysis, regression analyses and an independent sample t-test.

Case subjects that appear out of the “norm” are those that are either above or below the general consensus, these are outliers that can have adverse effects on statistical results (Hair, Black, Babin & Anderson, 2010:65; Pallant, 2013:127-128). To detect if any outliers were present in this data set the Mahalanobis statistic was computed. This study comprised four variable constructs, as such any Mahalanobis statistic larger than 18.467 (chi-square value for $\alpha = 0.001$ at 4 df) was considered to be an outlier and would consequently be liable for removal from the data set. The constructs were set as independent variables, while the classifying case numbers were set as a dummy dependent variable. Once computed, IBM SPSS Statistics 27 produced the 10 highest Mahalanobis distance statistics of the data set. These figures can be seen in Table 1 below.

Table 1: Outlier statistics

| | Case Number | Statistic |
|-----------------|-------------|------------|
| Mahal. Distance | 1 | 6 |
| | 2 | 179 |
| | 3 | 364 |
| | 4 | 84 |
| | 5 | 290 |
| | 6 | 493 |
| | 7 | 453 |
| | 8 | 156 |
| | 9 | 152 |
| | 10 | 227 |

Note: Bold cases were deleted

As Table 1 indicates, 8 of the top 10 Mahalanobis statistic values were greater than that of 18.467 (chi-square value for $\alpha=0.001$ at 4 df). As such, these 8 cases exceeded the cut-off level, they were subsequently deleted from the data set. This left 492 viable case responses for statistical analysis.

4.1 Internal-consistency reliability

To test the reliability of the measuring constructs the Cronbach’s alpha statistic was used. Cronbach’s alpha values equal to or greater than 0.70 indicate good to excellent reliability, while values below 0.50 are considered unacceptable (Zikmund & Babin, 2013:257; Malhotra, 2010:319). The results of the Cronbach’s alpha analysis can be found in Table 2.

Table 2: Reliability analysis

| | Items (n) | Cronbach’s alpha |
|----------------------|-----------|------------------|
| Subjective norms | 3 | 0.81 |
| Health consciousness | 3 | 0.86 |
| Purchase intention | 3 | 0.90 |
| Purchase behaviour | 4 | 0.85 |

The measuring constructs all produced Cronbach’s alpha values of above the recommended level of 0.70, indicating excellent reliability. Purchase intentions of organic food products recorded the highest score of 0.90, while the remaining constructs all achieved Cronbach’s alpha values above

0.80. Thus, it can be inferred that the measuring instrument displays a good internal-consistency reliability.

4.2 Descriptive statistics

The data sets' descriptive statistics were computed simultaneously with a sample t-test. This was conducted in order to assert both the data's characteristics and the significance of the construct means. The captured data were measured using a 6-point Likert scale, as such the expected mean was set at a level of 3.00. The significance level was set at the conventional $\alpha = 0.05$. The results are shown in Table 3 below.

Table 3: Descriptive statistics

| | N | Means | SD | t-value | p-value | Skewness | Kurtosis |
|----------------------|-----|-------|------|---------|---------|----------|----------|
| Subjective norms | 492 | 4.74 | 0.98 | 108.21 | 0.000 | -0.97 | 1.25 |
| Health consciousness | 492 | 4.74 | 1.01 | 103.34 | 0.000 | -0.89 | 0.77 |
| Purchase intention | 492 | 4.73 | 0.98 | 107.52 | 0.000 | -1.04 | 1.85 |
| Purchase behaviour | 492 | 4.40 | 1.05 | 92.51 | 0.000 | -0.73 | 0.36 |

p-value: two-tailed significance

As Table 3 shows, measuring constructs achieved a mean greater than that of 3.00 and each construct's mean was statistically significant at the $p \leq 0.05$ level. These results imply that Generation Y consumers heed the opinions of their peers in a significant manner. Moreover, these consumers are health conscious in terms of the type of food they purchase. In terms of Generation Y consumers' organic food purchase intentions and behaviour it can be noted that these individuals display both positive future intentions and purchase behaviour towards organically grown products.

The data sets distribution or normality fell within the recommended range of -2 and +2 for skewness, as well as between -7 and +7 for kurtosis (Kalkbrenner, 2022; Berndt & Petzer, 2011). As such, there were causes of concern regarding the data's distribution.

4.3 Correlations analysis

To determine if any relationships were present between the measuring construct's variables, a Pearson's product-moment coefficient was conducted. The relationship strengths were identified using the average means, which ranged from 0 to 1. Identification of strength included a Pearson value (r) of $r \geq .50$, which represents a strong associating relationship, $r \geq .30$, which indicates a fair relationship and $r \geq .10$ which infers a weak relationship between construct variables (Pallant, 2016:150; Pallant, 2013:139). The correlation matrix is displayed in Table 4.

Table 4: Correlation matrix

| Constructs | 1 | 2 | 3 | 4 |
|----------------------|---------|---------|---------|---|
| Subjective norms | 1 | | | |
| Health consciousness | .553**S | 1 | | |
| Purchase intention | .534**S | .659**S | 1 | |
| Purchase behaviour | .582**S | .678**S | .782**S | 1 |

**Correlation is significant at the 0.01 level (2-tailed)

W = Weak relationship; M = Moderate relationship; S = Strong relationship

The results in Table 4 show that all construct variables had a statistically significant positive relationship amongst each other. Furthermore, each variable relationship was a strong associated relationship as all Pearson coefficients exceeded 0.50 ($r \geq .50$). The weakest yet still strong relationships were between subjective norms and purchase intention ($r = 0.534$, $p = 0.000 < 0.01$),

health consciousness ($r = 0.553$, $p = 0.000 < 0.01$) and purchase behaviour ($r = 0.582$, $p = 0.000 < 0.01$). The strongest associated relationship was found between purchase intention and purchase behaviour ($r = 0.782$, $p = 0.000 < 0.01$). This association is to be expected as these constructs are closely related in the literature (Greaves *et al.*, 2013:111; Kim *et al.*, 2013:258; Chan & Bishop, 2013:96; Mostafa, 2007:448). The results indicate that Generation Y consumers' organic product buying behaviours are favourable and these consumers show a strong affection to their peers acknowledging a healthier lifestyle. This is evident by the showcase of the strong relationships between the independent construct variables and the dependent variable purchase behaviour.

No concerns for multicollinearity were present as none of the correlation coefficients exceeded 0.90. Furthermore, each pair of latent factors displayed a significant correlation at the 0.01 level, this implies that the data has nomological validity (Malhotra, 2010:321).

4.4 Regression analysis

A regression analysis was employed to determine how much predictability the factors of subjective norms, health consciousness and purchase intentions of organic products have towards organic product purchase behaviour. The regression analysis results are presented in Table 5.

Table 5: Regression analysis

| | Standardised Beta | Adjusted R ² | t-value | Significance level |
|---|-------------------|-------------------------|---------|--------------------|
| Dependent variable: Purchase behaviour | | | | |
| Independent variables: | | | | |
| Subjective norms | 0.166 | | 5.168 | 0.000* |
| Health consciousness | 0.288 | | 6.327 | 0.000* |
| Purchase intentions | 0.543 | 0.674 | 15.267 | 0.000* |

*Significance at the 0.05 level (2-tailed)

As Table 5 depicts, Generation Y consumers' purchase behaviour is significantly positively influenced by subjective norms ($\beta = 0.166$, $p = 0.000 < 0.05$), health consciousness ($\beta = 0.288$, $p = 0.000 < 0.05$) and purchase intentions ($\beta = 0.543$, $p = 0.000 < 0.05$). It is noteworthy to point out that purchase intentions had the largest contributing effect to purchase behaviour with a β value 0.543, these results are prevalent within current literature (Greaves *et al.*, 2013:111; Kim *et al.*, 2013:258; Chan & Bishop, 2013:96; Mostafa, 2007:448). The three independent variables together explained 67 percent of the variance in purchase behaviour. As such, it is evident that the independent factors successfully predict Generation Y consumer organic product purchase behaviour.

4.5 Independent samples t-test

Environmental issues are often prone to gender bias, that being females are generally considered to be the more environmentally concerned gender. This sentiment echoes as females are often associated with doing household food purchases, such as organic food purchases. Therefore, to determine if there were gender differences present in Generation Y consumers' organic food purchases, an independent samples t-test was implemented on the data set. The results can be found in Table 6.

Table 6: Gender difference

| Constructs | Gender differences | | | | t- value | p-value | Cohen's d | |
|----------------------|----------------------------|--------------|------------|----------------|----------|---------|-----------|--------------|
| | Male n=241 Female n=249 | Male Mean | Male SD | Female Mean | | | | Female SD |
| Subjective norms | | 4.751 | 0.973 | 4.733 | 0.973 | 0.198 | 0.757 | ***** |
| Health consciousness | | 4.755 | 1.048 | 4.730 | 0.989 | 0.263 | 0.479 | ***** |
| Purchase intention | | 4.673 | 1.037 | 4.800 | 0.916 | -1.437 | 0.160 | ***** |
| Purchase behaviour | | 4.461 | 1.057 | 4.336 | 1.053 | 1.313 | 0.744 | ***** |

* Statistically significant at $p < 0.05$
 ** Small effect, practically non-significant
 *** Medium effect and moving towards practical significance
 **** Large effect, practically significant
 ***** Cohen's d statistic not calculated as the variable was not statistically significant

Table 6 shows that there were no statistical differences between male and female respondents for all the constructs, as each construct's p-value was greater than 0.05. As a result, there was no need to calculate Cohen's d statistic. These results are indicative that both male and female Generation Y consumers view the same level of importance with regard to organic food products.

5. CONCLUSION

The physical well-being of the environment will continue to have a profound effect on future consumers' purchase patterns and views. Environmental concern experienced by consumers support this fact, regardless of the motive of change in purchase behaviour. As environmental problems are generally complex and large-scaled problems, including climate change, fuel emissions, forest degradation and the like, the easiest way for consumers to make a change/difference would be to purchase environmentally friendly products on a small scale. Furthermore, these purchases serve a double purpose, one is the physical well-being of the environment and two is the health benefits for the consumer. As such, the organic food market has become an industry to take note of, especially among the youth of South Africa. Currently, the Generation Y cohort holds major economic control, their social needs for a better, cleaner, "greener" lifestyle will shape the future direction of consumerism. Therefore, it is imperative to understand what factors drive this cohort in terms of their food purchase decisions.

This study showcases the blatant concern the Generation Y cohort has towards consuming organic products. Their social status, opinions of loved ones and health concerns over their food purchases are prevalent in the South African market. Therefore, it may be concluded that this generation displays a positive intent to not only purchase organic foods but also adopt a healthier lifestyle for themselves and future generations. Consequently, the organic food market in South Africa must consider expanding the current organic market offerings. Similarly, food producers must reconsider their own business practices in terms of where they source and how they source their food products in order to capture this new eco-friendly market.

THE RELATIONSHIP BETWEEN ORGANISATIONAL CULTURE AND AFFECTIVE COMMITMENT WITHIN AN AGRICULTURAL ORGANISATION

M. Borchardt

North-West University, Mahikeng, South Africa

H. Van Schalkwyk

North-West University, Mahikeng, South Africa

ABSTRACT

The South African agricultural sector is vital to the economy and the overall welfare of the country. The primary agricultural sector, as a consequence, must function effectively and efficiently. Private agricultural retail organisations are indispensable, especially in many of our predominantly rural areas. However, the importance of these organisations does not preclude them from adverse employee behaviour. Thus, this study investigated organisational culture to help come to an understanding of how it can contribute to Organisational Commitment in enhancing the contributions of organisations to the economy. Information was obtained by means of a questionnaire developed to measure organisational culture and affective commitment dimensions. The questionnaire was applied in a cross-sectional survey to a sample of 277 employees of a private agricultural retail organisation. The study aimed to determine whether cultural dimensions can predict Affective Organisational Commitment (which contributes to the overall Organisational Commitment of staff). Cultural dimensions such as Coordination, Growth and involvement, and Autonomy were identified to have contributed to adverse employee behaviour. Moreover, these respective cultural dimensions contributed significantly to the prediction of Affective Commitment. This study contributes to the contextual knowledge regarding the relationships between organisational culture and affective commitment. Furthermore, effective human resource management practices increased staff commitment, specifically through affective commitment in (agricultural retail) organisations. It would thus be prudent for agricultural organisations to develop and adapt their human resource management processes to enhance relevant dimensions of organisational culture such as Coordination, Growth and Involvement, and Autonomy, which showed viability in predicting affective organisational commitment.

1. INTRODUCTION

Organisational culture significantly impacts employee retention; as such, the analysis and its effect on employees' Organisational Commitment are of utmost importance (Wentong et al., 2021:10-11; Anitha & Begum, 2016). The resource management model explains how the effective management of organisational human and other resources contributes to the collective organisational commitment of employees and ultimately enhances the organisation's performance (Aboramadan et al., 2019:165; Barrick et al., 2015). Thus, employees need to be conscious of the fact that they are contractually obliged to meet organisational goals once employed by an organisation. Employees, similarly, usually harbour certain expectations towards the organisation

itself. For this reason, organisations should clarify what they expect and concomitantly determine what employees expect.

Expectancy theory states that individuals are more motivated when their expectations are met (Baciu, 2017:147; Greenberg & Baron, 2003). These expected returns may relate to an individual's needs, as is evident from Abraham Maslow's needs hierarchy (Baciu, 2017:147; Bratton et al., 2005) which illuminates the variety of interrelated needs: Sustenance, safety, belonging, affection, and personal growth. Some of these needs can be met (and employees can be motivated) through remuneration, but others cannot. Here, human resource (HR) management practices and processes can develop integrated strategies aimed at acquiring, retaining, and adequately motivating employees intrinsically and extrinsically (Miško et al., 2021:1059; Dale, 2003) that will assist the organisation in realising its goals (Habib et al., 2018:65; Seunghoo et al., 2017:106; Greene, 2011). However, incorrectly implemented human resource strategies may contribute to failures within the organisation (Ogbonnaya & Messersmith, 2019:512; Watty-Benjamin & Udechukwu, 2014; Gurbuz & Mert, 2011). A thorough analysis and understanding of the HR practices are therefore vital. These practices may influence staff commitment (Roper, 2011; Rowley & Jackson, 2011) or contribute to staff turnover (Hans, 2021:382; Allen et al., 2010).

Extensive research regarding the associations between HR activities and organisational commitment exists. Numerous scholars (Hans, 2021:382; Steyn et al., 2017; Bashir & Long, 2015; Coetzee et al., 2014; Renaud et al., 2014; Nujjoo & Meyer, 2012; Yang, 2010) have identified positive links between effective HR practices such as high-involvement and capability development practices which includes training and fair rewards (specifically intrinsic reward) and Affective Commitment to the organisation. Furthermore, managerial actions, job characteristics, and facets of compensation are aspects that members of organisations interpret (Ashkanasy et al., 2011). Whether negative or positive, these interpretations may influence employee behaviour. Thus, when analogous interpretations of human resource management and other managerial practices implemented within the different organisational groups are made, the dimensions of organisational culture are shaped (Abdullah et al., 2022:8).

Research regarding organisational culture and affective commitment within agricultural organisations seems to be limited. International scholars (Patricia et al., 2017:170; Howell et al., 2012) found that organisational values play an essential role in affective commitment outcomes. Local evidence indicates that employees remain committed to the organisation when they are satisfied with their jobs (Mafini & Dlodlo, 2014). Moreover, Lee et al. (2018:1195) and Manetje and Martins (2009) indicated that organisational culture influences affective organisational commitment. According to Tashtoush and Eyupoglu (2020:2) and Fisher (2014:724), emotional reactions to work practices may influence employee behaviour. Therefore, an organisation can positively influence employee retention, increase productive behaviour, and enhance well-being through affective commitment (Samuel & Engelbrecht, 2021:7; Manetje & Martins, 2009:109). Employee well-being can thus aid in staff retention and lower staff turnover, which is a net positive for an organisation.

Staff retention is a critical component of a successful organisation as there are consequences of a high staff turnover such as loss of skills and experience, a decrease in competitiveness, and extra recruitment expenses (Barnard et al., 2012; Allen et al., 2010; Local Government Sector Education and Training Authority [LGSETA], 2019:54). These factors may threaten the long-term existence

and profitability of the organisation. According to Mashile et al. (2021: 391) and Neelam et al. (2013), one of the main reasons for high staff turnover is the inability of employees to tolerate the prevailing organisational culture.

This study attempts to determine whether correlations exist between organisational culture and affective commitment within the agricultural organisation. This is to determine whether such dimensions of culture could be used to predict organisational commitment. Moreover, the present study does not focus on identifying the elements of culture or on diagnosing the types of culture that exist, as extensive research has been conducted by scholars such as Abbaspour and Noghreh (2015), Denison et al. (2014), Dwivedi et al. (2013), Asmawi and Mohan (2011) and Lok et al. (2005). Instead, the study will attempt to identify the weaknesses within an organisational culture that contribute to lower staff commitment levels and higher staff turnover and it furthermore analyses organisational culture and affective commitment to provide possible reasons for high staff turnover.

2. LITERATURE REVIEW

2.1 Conceptual framework

Organisational culture and cultural dimensions

In the extant literature, key elements defining organisational culture include uniform moral values, customs, principles, and behaviours that establish a general background for all deeds and thoughts within the organisation (Liu et al., 2022:4; Jain, 2015:2; Asmawi & Mohan, 2011; Mullins, 2010; Keyton, 2005). It is a spontaneous, shared approach to identifying what unites and influences how employees self-reflect (Wagner & Hollenbeck, 2005). According to Alverson (cited by Ashkanasy et al., 2011), the type of culture that exists within an organisation should: reflect mutual views, symbols, and beliefs within the group; provide simple rules and beliefs to which its employees are devoted; and direct employees on how feelings and affections ought to be communicated. Therefore, the organisational culture within the present study will be viewed as “principles and behaviours that establish a general background for all deeds and thoughts within the organisation that influence how employees self-reflect” (Asmawi & Mohan, 2011). This study will explore the organisation’s expectations of employee behaviour and how these expectations influence how employees self-reflect. According to Mashile et al. (2021:386), if an organisation’s expectations make an employee feel undervalued, it might contribute to the employee’s negative interpretations, resulting in less commitment and even resignation. The agricultural organisation that participated in this study experienced negative employee behaviour and high turnover, highlighting the importance of and need to understand the reasons for such outcomes.

Cultural dimensions and affective commitment

The most common dimensions of organisational culture (which have been isolated in various previous studies) were considered for analysis. Originally eight of these dimensions, as identified in a study by Dwivedi et al. (2013), were considered. However, after exploratory factor analysis, only three were deemed viable.

Coordination: Wendry et al. (2022:2) and Denison et al. (2014) defined coordination as the collective effort of diverse operations and divisions within an organisation to accomplish shared

objectives. According to Asmawi and Mohan (2011), coordination entails the involvement of different organisational divisions to direct cooperation. Quinn and Worline (cited by Cameron & Spreitzer, 2012) concluded that there is a relation between coordination and shared cultural identity among individuals in an organisation.

Growth and involvement: Denison et al. (2014) referred to growth and involvement as the continuous commitment of organisations to improving their employees' capabilities to remain competitive and the individual's engagement with organisational staff. By engaging employees, organisations can assist individuals with personal growth. Employees become involved when requested to improve the organisation's strategy and decision-making (Asmawi & Mohan, 2011). Thus, the management of employees can be facilitated through involvement (Neelam et al., 2013), and involvement can revive their commitment to the organisation (Imran & Ismail, 2022:3382; Kraus, 2014). Furthermore, Singh and Gupta (2015) stated that individuals with high levels of participation in their occupations become emotionally attached to the organisation.

Autonomy: According to Dwivedi et al. (2013), an experience of autonomy means that employees feel a sense of independence to function in their domain. This will enhance their enthusiasm for their duties and encourage them to fearlessly exercise their authority while assisting others to do the same. Autonomy may reduce the pressure employees experience in the working environment (Havermans et al., 2017:2) and revive or lead to staff commitment (Kraus, 2014; Sekhar, 2011). Neelam et al. (2015) indicated that the cultural element of perceived autonomy impacts an employee's level of emotional attachment to the organisation.

The implications of the Affective Commitment outcome

There are different ways in which staff members may manifest or demonstrate their commitment to an organisation. When employees are normatively committed to the organisation, they work for it because they feel ethically obliged to do so (Usman et al., 2021:209; Choo et al., 2016; Dwivedi et al., 2013). In terms of continuance commitment, employees continue working for an organisation because they consider the cost of resigning too high (Usman et al., 2021:209; Dwivedi et al., 2013; O'Driscoll & Randall, 1999). However, organisations should strive for affective commitment as employees remain at organisations when they are passionate about their jobs (Usman et al., 2021:209; Dwivedi et al., 2013; Pierro et al., 2013; Simintiras et al., 2012; O'Driscoll & Randall, 1999). Irrespective of any prevailing conditions, this commitment will make the organisation emotionally difficult to leave or neglect (Usman et al., 2021:209). However, if employees feel emotionally drained, their level of commitment might be low, increasing their intention to resign (Ladebo, 2009). Human resource management (HRM) practices that accommodate employees' values might contribute to a higher emotional commitment from employees (Mullins, 2010). According to Greenberg and Baron (2003), it is unlikely that dedicated employees will resign from an organisation. Hence, in the present study, the hypothesis is that there is a relationship between cultural dimensions and affective commitment. Furthermore, the degree of affective commitment will indicate employees' intentions of resigning, as elements of organisational commitment were the most accurate predictors of intention to resign (Allen et al., 2010).

3. METHODOLOGY

3.1 Research design

The agricultural organisation used in this study initially operated as a single venture for most of its existence. However, it transitioned and became part of a cooperative society. In such societies, various organisations join forces in owning and managing an organisation for a common goal, which is most often monetary, social, and ethos gains (Anonymous, 2016). As the newly joined team of managers may possess different skills, this type of society may also give rise to challenges such as a deficiency in managerial skills (e.g., interactive human skills) (Anonymous, 2016), which in its turn may discourage good performance and synergy amongst employees. Therefore, it was important for this study to identify the challenges that employees face that may be management specific. This required that the biographical information of respondents, HRM practices, and outcomes be analysed and compared as some of the information obtained and the existing research may also be sector specific. The differences exist in employee information and its role in terms of what employees value and expect. In order to measure the various relevant variables related to these concepts, participants completed a questionnaire in a cross-sectional survey; thus, a quantitative research approach was followed.

3.2 Sampling method

The study was conducted in a private organisation comprising six business units (abattoirs, agricultural products trade, building material trade, consultation and administration, motor vehicle trade, and petroleum trade) distributed throughout one of the South African provinces. The population was clustered in regional areas, and the clusters were selected to represent the six business units. A sample of 277 participants was drawn from a population of 760 staff members (i.e., a 36% sample – see Table 1), and the business units were also adequately represented by similar percentages (see Table 1). This sample should represent the population adequately in terms of a rule of thumb (a 30% sample from a relatively small population) noted by Terre Blanche et al. (2006).

3.3 Research instrument

The initial instrument was developed for a broader study. The full version of the questionnaire consisted of Sections A-E (see Borchardt, 2016; Annexure A). The sections important to this article include a questionnaire to elicit responses regarding biographical details in Section A (Table 1). Section B (Borchardt, 2016) was developed with questions regarding HRM practices implemented by managers relative to the 8 OCTOPACE dimensions of culture (Dwivedi et al., 2013). Section D contained questions to determine the affective levels of Commitment (Greenberg & Baron, 2003). Five-point Likert-type interval scales (strongly disagree to neutral to strongly agree) were used in Sections B and D. All subscale items were phrased positively to facilitate comprehension for respondents with low levels of schooling. To this end, items were also translated from English into the home language of the majority of respondents.

3.4 Data collection

A questionnaire was developed to measure the variables as indicated above. Examples of the questions for the amended questionnaire can be found in Appendix A. Consent to survey employees was obtained from top management, who informed all staff members. A letter to

explain the research project’s purpose was sent to the different business units. Regional clusters were identified to represent the population of staff members, suitable venues were booked, and the individuals were informed by their business unit management when and where to present themselves to participate in the survey. Participants were assured that their participation was voluntary, that their anonymity was assured, and that the data gathered would be confidential. To this end, each participant was invited to sign a consent form. Printed versions of the questionnaires were presented to participants during the group sessions to complete individually, and the researcher and an assistant attended to queries. The researcher obtained ethical clearance from the Ethical Committee of the North-West University to conduct the study.

3.5 Data analysis

Data analysis was conducted using SPSS for Windows. Data was tested using factor analysis and tested for validity and reliability. Moreover, descriptive analytics were conducted as well as regression analysis.

4. RESULTS AND DISCUSSION

4.1 Results

Demographic analysis

Demographic analysis was conducted, testing for age, qualifications, position, tenure, and business unit. The following table shows the findings of the demographic analysis, followed by a discussion of the data presented in Table 1.

Table 1: Demographic characteristics of participants

| Variables | Characteristics | Frequency | Percentage |
|-----------------------------------|---------------------------|-----------|------------|
| Age groups | 16 – 27 | 85 | 30.7 |
| | 28 – 37 | 79 | 28.5 |
| | 38 – 47 | 65 | 23.4 |
| | 48 – 57 | 33 | 12 |
| | 58 – 67 | 13 | 4.7 |
| | Missing | 2 | 0.7 |
| Qualification levels | No schooling | 5 | 1.8 |
| | Primary school | 33 | 12 |
| | Secondary school | 200 | 73 |
| | College credit, no degree | 22 | 8 |
| | University degrees | 13 | 4.7 |
| | Missing | 4 | 1.4 |
| Positions | Intern/casual | 4 | 1.5 |
| | Entry-level/permanent | 243 | 89 |
| | First-line management | 15 | 5.5 |
| | Middle management | 11 | 4 |
| | Top Management | 0 | 0 |
| | Missing | 4 | 1.4 |
| Tenure in current position | < 1 month | 1 | 0.4 |
| | 1 – 6 months | 43 | 15.5 |
| | 7 – 12 months | 45 | 16.2 |
| | 1 – 2 years | 56 | 20.2 |
| | 2 – 4 years | 53 | 19.1 |
| | 4 – 7 years | 28 | 10.1 |
| | 7 – 10 years | 15 | 5.4 |
| | 10 – 20 years | 22 | 7.9 |
| | > 20 years | 8 | 2.9 |
| | Missing | 5 | 1.8 |

| Variables | Characteristics | Frequency | Percentage |
|----------------|------------------------------|-----------|------------|
| Business units | Abattoirs | 40 | 36 |
| | Agricultural products | 111 | 38 |
| | Building materials | 30 | 35 |
| | Consultation, administration | 16 | 36 |
| | Motor vehicle trade | 31 | 36 |
| | Petroleum trade | 50 | 35 |

N = 277

The mean age of participants was 35 years (SD = 11.5; Median = 34), and 85 participants (30.7%) and 79 participants (28.5%) were from the 16 – 27 and 28 – 37 age groups, respectively (see Table 1). The relatively high percentage of employees (52.3%) who have been in their current position less than two years (see Table 1) attested to the high staff turnover rate experienced by the organisation.

It is also evident from Table 1 that most of the participants (86%) received secondary, primary or no schooling. Furthermore, very few participants (9%) were managerial staff (top management did not participate in the study), while most (89%) were entry-level/permanent non-managerial staff (see Table 1).

Factor analysis

To investigate the construct validity of the subscales, an exploratory factor analysis (EFA) was conducted through a principal component analysis with varimax rotation to facilitate the identification and interpretation of factors (see Field, 2009).

TABLE 2: Number of items, range of factor loadings

| Subscales | Items | Range factor loadings |
|----------------------|-------|-----------------------|
| Autonomy | 5 | 0.563 – 0.737 |
| Coordination | 6 | 0.458 – 0.703 |
| Growth & Involvement | 7 | 0.604 – 0.710 |
| Affective Commitment | 5 | 0.699 – 0.784 |

N = 277

A Kaiser-Meyer-Olkin (KMO) measure = 0.616 verified the sampling adequacy as “mediocre” but acceptable (KMO > 0.5) (Field, 2005), and Bartlett’s test of sphericity with $\chi^2(277) = 0.622$ $p = 0.00$ indicated that the correlations among items were high enough for the EFA (Field, 2005). Kaiser’s criterion of eigenvalues > 1 was used to identify 18 factors (Table 2). The relatively high factor loadings (all > or close to 0.5) of the different subscales and items measuring them (Table 2) attested to the construct validity of the subscales. Three dimensions of culture were identified: autonomy, cooperation, and growth and involvement. Subscale items with factor loadings higher than 0.40 were considered for interpretation in the study (Wiid & Diggins, 2013). From Table 2, the respective factor loadings provide sufficient evidence of the construct validity (Clow & James, 2014) of the relevant subscales. Similarly, the construct validity of the affective = commitment subscale was investigated, and the factor loadings of the five identified subscale items ranged from 0.699 to 0.784 (see Table 2), supporting the construct validity of this subscale.

4.2 Descriptive statistics

The following table shows the mean, standard deviation, skewness and Cronbach’s alpha for the variable’s autonomy, Coordination, growth and involvement, and affective commitment.

TABLE 3: Descriptive statistics for the subscales of three dimensions of Culture – Autonomy, Coordination, and Growth and Involvement

| Statistics | Mean | Standard deviation | Skewness | Cronbach's α |
|----------------------|-------|--------------------|----------|---------------------|
| Autonomy | 3.130 | 1.080 | -0.310 | 0.800 |
| Coordination | 3.760 | 0.980 | -0.600 | 0.830 |
| Growth & Involvement | 3.590 | 1.050 | -0.580 | 0.860 |
| Affective commitment | 3.260 | 1.220 | -0.300 | 0.910 |

N = 272

Autonomy

The mean of 3.13 (SD = 1.08) of the Autonomy scale falls in the 'neutral' category (ranging from 2.5 to 3.49) of the 5-point Likert scale, and the skewness = -0.31 indicates a slight build-up of values greater than the mean in the upper tail of the distribution. Sufficient Cronbach's alpha was achieved at 0.800.

Coordination

The mean of 3.76 (SD = 0.98) of the Coordination scale falls in the 'agree' category (ranging from 3.5 to 4.49) of the 5-point Likert scale, and the skewness = -0.60 indicates a slight build-up of values greater than the mean in the upper tail of the distribution. Sufficient Cronbach's alpha was achieved at 0.830.

Growth and Involvement

The mean of 3.59 (SD = 1.05) of the Growth and Involvement scale falls in the 'agree' category (ranging from 3.5 to 4.49) of the 5-point Likert scale, and the skewness = -0.58 indicates a slight build-up of values greater than the mean in the upper tail of the distribution. Sufficient Cronbach's alpha was achieved at 0.910.

Affective Commitment

The mean of 3.26 (SD = 1.22) of the Affective Commitment scale falls in the 'neutral' category (ranging from 2.5 to 3.49) of the 5-point Likert scale, and the skewness = -0.30 indicates a slight build-up of values greater than the mean in the upper tail of the distribution. Sufficient Cronbach's alpha was achieved at 0.800.

Predicting Affective Commitment based on cultural dimensions Autonomy, Coordination, and Growth and Involvement

A stepwise multiple regression analysis was conducted to determine whether the predictor variables (Autonomy, Coordination, and Growth and Involvement) could be used to predict the outcome/dependent variable, Affective Commitment.

TABLE 4: Regression model summary: Predicting Affective Commitment based on Autonomy, Coordination, and Growth and Involvement

| Model | R | R ² | R ² adj. | Std Error Est | Change statistics | | | | Durbin-Watson |
|----------------|-----|----------------|---------------------|---------------|-------------------|--------|---------|------|---------------|
| | | | | | R ² | F | Df: 1:2 | P | |
| 1 ^a | .61 | .38 | .37 | 4.85 | .38 | 163.81 | 1;273 | .00 | |
| 2 ^b | .65 | .42 | .41 | .41 | .04 | 19.13 | 1;272 | .00 | 2.04 |
| 3 ^c | .66 | .43 | .43 | .43 | .02 | 8.64 | 1;271 | .004 | |

a. Predictors: (constant), Coordination

b. Predictors: (constant), Coordination, Growth and involvement

- c. Predictors: (constant), Coordination, Growth and Involvement, Autonomy
- d. Dependent variable: Affective Commitment

From the regression model summary in Table 5, the constant plus predictor variable Coordination (38%; $F(1,273) = 163.81, p = .00$), Coordination plus Growth and Involvement (42%, $F(1,272) = 19.13, p = .00$) and Coordination plus Growth and Involvement plus Autonomy (43%, $F(1,271) = 8.64, p = .004$) contribute statistically significantly (a total of 43%) to the prediction of the dependent variable, Affective Commitment.

The R^2 and adjusted R^2 in model 3 (see Table 5) do not differ; therefore, the implication is that the model can be generalised to the population and the Durbin-Watson value of 2.04 implies that residuals are independent (i.e., errors are uncorrelated).

The average variance inflation factor (VIF) of 1.67 for model 3 is well below 10, and none of the tolerance values is below 2; thus, multicollinearity is not indicated (Field, 2009:242). It is evident from the above statistics that model 3 (see Table 5) is adequate in predicting affective commitment based on predictor variables coordination, growth and involvement, and autonomy.

5. DISCUSSION

According to Neelam et al. (2013), an intolerable culture is the main reason employees resign, and according to Anitha and Begum (2016), the organisational culture has a significant impact on the retention of employees. The results show that the coordination dimension contributed 38 per cent to the prediction of affective commitment. Therefore, employees from the different divisions worked well together to reach a common goal, making them feel more committed to the organisation. The participants' mean score on coordination was 3.76, which is relatively low on a 5-point scale. This result implies room for improvement of the employees' coordination, as coordination contributes the most to their level of affective commitment. Such an improvement in coordination will, in turn, also enhance commitment to the organisation substantially and decrease staff turnover proportionately.

The research results indicate that the growth and involvement dimension contributed 4 per cent – representing the second-highest contribution – to the prediction of affective commitment. Thus, granting employees growth and involvement opportunities increase their commitment to the organisation. The participants' mean score on growth and involvement was 3.59, which is also relatively low on a 5-point scale. This result implies some room for improvement in the organisation's Growth and Involvement efforts, which will also enhance their commitment to the organisation and potentially decrease staff turnover.

The cultural dimension of autonomy contributed 2 per cent – representing a minor contribution – to the prediction of Affective Commitment. This implies that the more autonomy employees experience, the more committed they feel toward the organisation. The participants' mean score on autonomy was 3.13, which is also relatively low on a 5-point scale. This result implies that there is room for improvement of the employees' feeling of autonomy, enhancing their commitment to the organisation and decreasing staff turnover.

Overall, it is evident that the organisation implements coordination initiatives for its human resources to work towards a common goal. However, there is still room for improvement in these efforts. Furthermore, when employees achieve the organisational goals, they might have some

expectations from the organisation's management in showing that they are valued. This does not only have to be shown in monetary terms, i.e., wages or salaries. The organisation can show the employees that they are valued by providing employees with opportunities for growth and more challenging work (Usman et al., 2021:209; Erasmus et al., 2015; Strydom, 2011). Fulfilling such expectations would be beneficial to the organisation, but more so for the employees, as it would improve their experience and skills to progress in their jobs and ultimately benefit the organisation. The demographic characteristics of the participants indicate that most employees (86%) hold no tertiary qualification, which highlights the need for growth opportunities. Most have worked for the organisation for more than one year, some for up to 20 years, but very few occupy managerial positions (9%). Also, most employees are between the ages of 16 and 37 years and who can still apply for other job opportunities to meet their experience and skills needs, should the agricultural organisation not be willing or able to assist them.

6. CONCLUSIONS

The present study strengthens the existing knowledge of researchers such as Ogbonnaya and Messersmith (2019:521) regarding the influence of specific dimensions of organisational culture on employees' levels of affective commitment to the organisation. It also highlighted the weak organisational culture dimensions that need improvement, such as coordination, training and involvement and autonomy initiatives to increase employees' affective commitment. However, these results contrast with the findings of Newman and Sheikh (2012), which revealed that autonomy and development initiatives did not significantly influence affective commitment among their Chinese respondents. This may be due to the difference in the political landscape of the two countries involved, namely China as opposed to South Africa. South Africa functions under a democracy. Employees, especially those from previously disadvantaged backgrounds, may view growth opportunities and autonomous practices as enabling and valuable.

Although coordination is evident within the organisation, respondents did not fully agree on its existence. However, since it is the most prominent reason employees are affectively committed and may eventually stay, it may reduce staff turnover. The agricultural organisation can improve its coordination initiatives by ensuring that clear authority and responsibility lines exist. The organisation can reward employees by providing more growth and involvement opportunities and training and development to enrich and enhance their jobs. These training and development initiatives will lead to greater levels of affective staff commitment (Bashir & Long, 2015; Coetzee et al., 2014; Yang, 2012). Furthermore, the organisation can also allow those who underwent training more ownership of their jobs, e.g., allowing them to make minor alterations in the way they carry out their jobs and thereby enhancing their feelings of autonomy. These efforts may very well assist the organisation in increasing its employees' level of affective commitment to the organisation, which should reduce the high staff-turnover level.

The study focused solely on an agricultural organisation in one of South Africa's nine provinces; any generalisations as regards the state of the agricultural industry in the country as a whole thus require a measure of caution. Moreover, only three dimensions of culture were isolated in the study and correlated with affective commitment. Numerous other dimensions could be explored in future research, strengthening the findings. Lastly, the study did not consider any reasons why an

employee may choose to terminate their employment and likewise did not provide any information on their reasons for leaving.

EXPLORING ENTREPRENEURSHIP MOTIVATIONAL FACTORS IN HIGHER EDUCATION SOUTH AFRICA

C.L. Mostert

North-West University, Potchefstroom, South Africa

L. Hamilton

North-West University, Vanderbijlpark, South Africa

ABSTRACT

The 4th Industrial Revolution is creating jobs and increasing unemployment simultaneously. Thus, Higher Education Institutions (HEIs) must demonstrate efforts to embrace and cultivate an entrepreneurial spirit among students, as they are the future of a country's prosperity. In South Africa, the entrepreneurial activity of the exiting cohort students within our HEIs is somewhat low. This creates concerns for the success of entrepreneurship development in the South African context. This study aimed to determine the factors that will motivate students at a South African Higher Education Institution (HEI) toward entrepreneurship. A self-administered questionnaire was distributed to collect the necessary and relevant data. This was done to explore the factors motivating Business Management students at a South African HEI towards entrepreneurial activity. Overall, 338 questionnaires were distributed for data collection, of which 319 questionnaires were completed and found suitable for data analysis. This effort signifies a response rate of 94 percent. The results indicated that greater business attainment, available entrepreneurial opportunities, job security, and independence were the main factors motivating Business Management students toward entrepreneurship. The findings are associated with previous research studies conducted on similar topics. The benefits of entrepreneurial activity, with specific reference to these four factors, can be highlighted by the HEI throughout the undergraduate studies of these students, and opportunities can be created for them to actively partake in entrepreneurial activities during their studies to start a business. Once they graduate, this will enable them to become job creators rather than job seekers. This specific HEI needs to reconsider the strategies for creating awareness of entrepreneurship as a career option. Furthermore, it is imperative to create ample opportunities for students to purposefully develop the skill to identify viable entrepreneurial opportunities, act on these opportunities, and manage the successful implementation of these opportunities within the South African context.

Keywords: Motivations; entrepreneurs; business management; students; South Africa

1. INTRODUCTION

It is an unquestionable fact that entrepreneurship contributes significantly to the economic growth of any country. This is evident in the well-documented literature on entrepreneurship and its importance (Matho and McDowell 2018; Örnek and Danyal 2015; Peng, Lu, and Kang 2012; West 2012; Kaushik 2013; Toma, Gregore, and Marinescu 2014; Khosla 2015). Entrepreneurship is considered a practice of constructing and capturing value for entrepreneurs that will ultimately underwrite economic and social prosperity in a country (Peng, Lu, and Kang 2012). Consequently, entrepreneurship has become an essential driver for job creation and achieving wealth among

individuals within a particular context (Barba-Sánchez and Atienza-Sahuquillo 2018). The global economic crisis in recent years has caused startlingly high unemployment rates (Barba-Sánchez and Atienza-Sahuquillo 2018). However, because there has been an intensification in creating awareness of entrepreneurship and the significant impact entrepreneurs have on economic development, policymakers now appreciate the importance of creating and endorsing a conducive entrepreneurial environment (Matho and McDowell, 2018; Ho et al., 2018).

Furthermore, it has also become apparent that many youths are interested in becoming entrepreneurs (Matho and McDowell 2018; Schøtt, Kew, and Cherangi 2015). Suppose the aim is to utilize entrepreneurship to its full potential in contributing to economic growth. In that case, it is of utmost importance to realize that the promotion of entrepreneurship exceeds efforts to assist and support entrepreneurs and business owners, but even more so to embrace and cultivate an entrepreneurial spirit among the youth in a country, as they will produce the upsurge of enterprises in the near future (Ho et al. 2018).

The Global Entrepreneurship Monitor highlights that South Africa exhibits low levels of business activity among all demographic groups and ages within their society (Herrington, Kew, and Mwanga 2017). However, a promising outcome of recent research found that the proportion of South African entrepreneurs with education at a tertiary level has progressively increased over the last couple of years (Herrington, Kew, and Mwanga 2017). Thus, the assumption can be made that education and training contribute significantly to management knowledge and the development of essential skills and behaviors of entrepreneurs (Paço et al., 2013). Because graduates will enter an environment functioning within the 4th Industrial Revolution, it is even more critical for HEIs to capitalise on opportunities to develop entrepreneurial intent and behaviour among students.

2. PROBLEM STATEMENT AND OBJECTIVES

When considering the fact that the 4th Industrial Revolution (4IR) is a significant role player in the business world, Higher Education Institutions must ask the question: *Are graduates prepared for the future as the 4IR is changing lives and economies rapidly?*

It is general knowledge that the 4IR is not only changing everyday lives, but it also changes how business is done. The 4IR implies an interchangeable relationship between individuals in the labour market, the business, and emerging technologies that remains inseparable from the 4IR. Thus, for graduates to endure this context and compete with these changes, academic knowledge is not adequate (Teng et al. 2019). Foo and Turner (2019) state that HEIs have an immense responsibility to ensure that graduates are equipped with the necessary skills and knowledge to function in and adapt to changes within the 4IR context. However, even though it is imperative to instill soft skills to ensure employable graduates, the high unemployment rate within the South African context remains a concern. Thus, HEI plays a vital role in preparing students as graduates within the 4IR but also equipping these students to become entrepreneurs actively seeking entrepreneurial opportunities in this specific context.

Students face numerous challenges within a uniquely South African context and now also need to consider the impact and effects of the 4IR. The 4IR simultaneously creates jobs and contributes to unemployment through technology's increased influence (Teng et al. 2019). Thus, students are increasingly confronted with the option of becoming job seekers or job creators. If HEIs can effectively identify the factors that motivate students toward entrepreneurial activity, they can

actively develop strategies for graduate job creators. The primary objective of this study was to explore the factors which motivate Generation Y students at a South African HEI toward entrepreneurial activity.

3. LITERATURE REVIEW

It is unmistakable that entrepreneurship is considered a fundamental instrument for economic growth and, even more so, development (Matho and McDowell 2018; Örnek and Danyal 2015; Peng et al. 2012; West 2012; Kaushik 2013; Toma et al. 2014; Khosla 2015; Balaraman et al. 2016). The Global Entrepreneurship Monitor stipulates that entrepreneurs contribute on at least three levels in their societies: job creation, employment, and well-being (Bosma and Kelley 2019). Furthermore, when considering the total entrepreneurial activity (TEA) rates (where the percentage of the adult populace that is progressing towards starting a new business or who have started a business in the previous three years is measured), the highest rate in 2018 was found in Angola (41%) which is regarded a low-income economy (Bosma and Kelley 2019).

Recent research also found that the primary age group of entrepreneurs ranged between 25-34 and 35-44. These entrepreneurs possibly have tertiary education and have the advantage of some work experience (Bosma and Kelley 2019). Even though this might be the case, high rates of entrepreneurship among youth (people between the ages of 18-24) were also apparent. Bosma and Kelley (2019) state that the fact that youth have the energy and motivation to become entrepreneurs, are encouraged by peers, and operates in an environment that reveals entrepreneurial prosperity, might underwrite this finding

3.1 Entrepreneurship in the South African Context

South Africa is considered an efficiency-driven economy, with a significant escalation in the number of individuals who have viewed entrepreneurship as a rewarding career choice since 2010 (Herrington et al. 2017). South African society indicated high measurement levels concerning entrepreneurship as a good career choice, high status to successful entrepreneurs, and the media attention entrepreneurship receives, representing a strongly affirmative societal attitude towards entrepreneurship (Herrington et al. 2017). However, granting the positive societal attitude towards entrepreneurship in South Africa, the Global Entrepreneurship Monitor found a persistent tendency of low entrepreneurial intention is still present (with entrepreneurial intention decreasing by more than one-third compared to 2013), which creates matters of great concern (Herrington et al. 2017). The concern is linked to the fact that entrepreneurship is seen as a driver of job creation and decreasing unemployment, but in the case of South Africa, the actual entrepreneurial intention is declining; thus the opportunity to contribute to economic prosperity through entrepreneurship is not optimally utilised. Furthermore, the GEM report also states that early-stage entrepreneurial activity proves to be somewhat low among the Generation Y cohort (individuals aged between 18-24 years), which adds to the concerns experienced for the success of entrepreneurship development in the South African context.

Unemployment rates within this cohort have increased from 32.7 % in 2008 to 36.1% in 2011 and were measured at 38.2% in 2018 (Herrington et al. 2017; Stats SA 2018). It is imperative to realise that the potential human resources and talents that individuals in the Generation Y cohort exhibit are currently underutilised and that it will have an undesirable influence on the future growth

prospects of South African society if it is not addressed (Herrington et al. 2017). Thus, after carefully considering those mentioned earlier, it is crucial to determine the factors motivating youth to engage in entrepreneurial activity to ensure a positive contribution to economic development and prosperity within the South African context.

3.2 Motivations for entrepreneurial activity and the role of Higher Education Institutions

According to Farhangmehr, Gonçalves, and Sarmento (2016), Higher Education Institutions (HEIs) specifically focus on educating students in entrepreneurship and business management, which permits them to become active participants within their regions that contribute to economic and social development. Thus, these HEIs have an imperative role in collectively developing the skills and competencies that will ultimately motivate the students towards active entrepreneurial activity (Farhangmehr, Gonçalves, and Sarmento 2016).

For HEIs to successfully contribute to an entrepreneurial culture among its students, it is essential to consider the impact of the factors that motivates them to consider entrepreneurship (Pruett et al. 2008). Pruett et al. (2008) have identified money status, lifestyle (free time), independence, creativity (sense of personal creative accomplishments), and equity-opportunity (resolving concerns about career, satisfaction, and fairness) as factors that motivate students to become entrepreneurs. Furthermore, research conducted by Eijdenberg and Masurel (2013) characterised motivation into push factors and pull factors, where aspects such as recognition (respect earned from friends), drive (willingness to put forth the effort), refugee effect (awareness of high rates of unemployment), inability to find paid work (cannot find a paid job), redundancy (person lost the previous job), and necessity (starting a business to satisfy basic needs) are viewed as push factors. The need for achievement (personal commitment to succeed), locus of control (a belief that personal actions directly affect the outcome), desire for independence, passion, goal-setting, self-efficacy, risk-taking, financial success, role models, innovation, and entrepreneurial effect are considered pull factors. Stefanovic, Prokic, and Rankovic (2010) stated that greater business achievement, independence, intrinsic factors, and job security are the primary motivators for entrepreneurs. More recently, Seun et al. (2017) found that achievement motives, desire for independence, entrepreneurial passion, tangible rewards, family/friends support, identified regulations, career options, risk-taking, ability to explore, and willingness to invest (which were categorised as intrinsic and extrinsic motives) are more specific factors that motivate youth towards entrepreneurship.

Obtaining insights into the factors that will motivate students in HEIs towards entrepreneurship will ultimately assist HEIs and policymakers in developing students' necessary skills and abilities to become successful entrepreneurs within their society. Consequently, this paper aims to explore the factors that motivate students, more specifically Business Management students, as they directly gain entrepreneurship education at a specific HEI in the South African context toward entrepreneurship.

4. RESEARCH METHODOLOGY

The research aimed to provide an overview of the factors that motivate Business Management students at a South African HEI towards increased entrepreneurial intention and activity. The research is of a descriptive nature, with a single cross-sectional approach. Students registered full-

time for Business Management modules, within the Faculty of Economic and Management Sciences at a South African HEI were identified and utilized as the target population for this research study. The sample frame consisted of one campus located in the Gauteng Province. The non-probability convenience sample for the main study consisted of 338 responses. A quantitative approach was followed, and a positivist approach was embraced to ensure the researcher remained objective towards the study, data collection, and actual research.

A semi-structured, self-administered questionnaire was distributed to collect the necessary and relevant data. This was done to explore the factors motivating Business Management students at a South African HEI towards entrepreneurial activity. The applicable sections of the questionnaire collected data on respondents' opinions regarding their perception of the influence of certain factors on their motivations to become entrepreneurs. In total, 14 items were analyzed for entrepreneurial motivation. This was determined on a four-point Likert scale, where respondents had to indicate the level to which they completely disagree (1), ranging to completely agree (4), with the scale items. The four-point Likert scale with the absence of a neutral item was used to provoke commitment to either a negative or positive opinion (Croasmun & Ostrom, 2011:20). In order to determine the reliability of the constructs within the questionnaire, a pilot was conducted with a convenience sample of 56 students. After the ethical clearance was obtained, the questionnaire was distributed to the students.

Overall, 338 questionnaires were distributed for data collection, of which 319 questionnaires were completed and found suitable for data analysis. This effort signifies a response rate of 94 percent. The results indicated that the sample included both male (38.0%) and female (62.0%) participants. In order to interpret and present a demographic profile of the respondents, descriptive statistics were used. Additionally, exploratory factor analysis was used to interpret and explore the factors that motivate students to increase entrepreneurial activity. Respondents' participation in this study was entirely voluntary, and the privacy and identity of the respondents were protected by guaranteeing that no personal information, including their names, was disclosed.

4.1 Data Analysis

The data collected from the completed, useful questionnaires were captured in Microsoft Excel. Statistical Package for Social Sciences (IBM SPSS), Version 25 for Windows, was used to process and analyse the captured data. For the entire scale measuring students' motivation for entrepreneurial activity, a Cronbach Alpha value of 0.836 was computed. This exceeds the recommended value of 0.70 (Brace et al. 2012) and therefore provides evidence of internal consistency reliability. The inter-item correlation mean of 0.282 provides further proof of reliability, which is also within the recommended range of 0.15 to 0.50 (Clark and Watson, 1995). Convergent and discriminant validity of the scale measuring the motivating factors for entrepreneurial activity is thus suggested.

4.2 Results and Discussion

The following sections provide an overview of the results relating to the demographic profile, respondents' intent to become entrepreneurs, and the motivating factors for entrepreneurship identified through exploratory factor analysis.

4.2.1 Demographic Profile of Respondents

This section explains the demographical results of the items within the questionnaire. Table 1 summarises the demographic profile of the respondents (percentages).

Table 1: Demographic Profile of Respondents

| Gender | | Age | | Race | | Years of Study | |
|------------|------|------------|------|------------|------|-----------------|------|
| Item Label | % | Item Label | % | Item Label | % | Item Label | % |
| Male | 38.0 | 18 | 4.8 | African | 83.5 | 1 st | 77.4 |
| Female | 62.0 | 19 | 20.6 | Coloured | 3.0 | 2 nd | 11.3 |
| | | 20 | 28.1 | Asian | 0.6 | 3 rd | 8.5 |
| | | 21 | 20.3 | White | 12.9 | 4 th | 0.9 |
| | | 22 | 12.6 | | | Hons | 1.9 |

Source: Author's compilation

From Table 1 it is evident that the majority of the respondents were females (62.0%), 20 years of age (28.1%), and of African race (83.5%). Concerning the current year of study, most students were in their first year of study (77.4%).

4.2.2 Respondents' Intent to Start a Business

In addition to this information, respondents were also asked to indicate whether or not they plan to start their own businesses. Table 2 provides an overview of the responses recorded.

Table 2: Intent to start your own business

| Item Label | Frequency | % |
|------------|-----------|------|
| Yes | 263 | 79.7 |
| No | 67 | 20.3 |

Source: Author's own compilation

Seventy-nine percent (79.9%) of the respondents reacted positively regarding their intent. Although the more significant number of the Business Management students partaking in this research study intend to start their own business, it remains imperative for the HEIs to capitalize on the motivations that will drive their ambition to actively pursue entrepreneurial opportunities, thus engaging in increased entrepreneurial activity.

Respondents were also asked to indicate their level of agreement with the statement relating to entrepreneurship and starting their own businesses. Table 3 provides an overview of the descriptive results relating to students' responses to each statement.

Table 3: Students' level of agreement with statements relating to entrepreneurship and starting their own business

| Item | Completely disagree (%) | Disagree (%) | Agree (%) | Completely agree (%) |
|---|-------------------------|--------------|-----------|----------------------|
| Have seriously considered entrepreneurship as a highly desirable career option. | 5.1 | 16.3 | 47.0 | 31.6 |
| Have never thought of entrepreneurship as a career choice. | 36.1 | 35.5 | 20.6 | 7.9 |
| Have already begun the planning for opening a new venture. | 18.8 | 38.5 | 32.1 | 10.6 |
| Will not start a new business because it is too risky. | 40.8 | 41.7 | 14.1 | 3.4 |
| Will not start a business because of fear of failure. | 45.9 | 37.7 | 12.8 | 3.6 |
| Could easily pursue a career involving self-employment if I wanted to. | 1.8 | 18.4 | 50.6 | 29.2 |

| Item | Completely disagree (%) | Disagree (%) | Agree (%) | Completely agree (%) |
|--|-------------------------|--------------|-----------|----------------------|
| Care what my closest family/friends think about my employment decision. | 22.5 | 32.1 | 35.4 | 9.9 |
| Believe that my closest family/friends think that I should become self-employed. | 13.0 | 37.0 | 36. | 12.4 |
| Care what my lecturers think about my employment decision. | 29.0 | 36.9 | 27.5 | 6.6 |
| I am interested in business because my family/friends are in business. | 33.4 | 44.6 | 16.6 | 5.4 |

Source: Author's own compilation

From the above table (table 3), it is evident that most respondents agree that they have seriously considered entrepreneurship as a career option (78.6%). They also indicated that aspects such as risk (82.5%) and fear of failure (83.6%) would not prevent them from starting their own business. Although most respondents indicated that they have seriously considered entrepreneurship a career option, only 42.7% of respondents agreed that they have already begun planning to open a new venture.

4.2.3 Motivational factors for entrepreneurship in higher education institutions

The study's main objective was to explore the motivating factors for entrepreneurship among Business Management students at a South African HEI. An exploratory factor analysis was used to measure the aforementioned. The Kaiser-Meyer-Olkin measure of sampling adequacy and the Bartlett test of sphericity were examined and used for the purpose of the analysis. This was done to determine the suitability of the principal component analysis. The Kaiser-Meyer-Olkin measure for this particular study was .891. According to Field (2009), this measure was acceptable.

Furthermore, the Bartlett test ($9 < .00001$) was also significant. Thus, reducing data through the principal component is justifiable (Pallant 2016). Four factors for the motivation of students to engage in entrepreneurial activity exist. A factor analysis with varimax rotation was performed on these four factors. This was used due to little correlation between the factors. Loadings of 0.45 were used for item inclusion, and an eigenvalue of 1 was used for factor extraction criteria, which resulted in the said four factors. The four factors were labeled as Greater Business Attainment (Factor 1), Available Entrepreneurial Opportunities (Factor 2), Job Security (Factor 3), and Independence (Factor 4). The eigenvalues for these four factors ranged from 0.785 to 5.108. For reliability analysis of the data, Cronbach's coefficients were examined for each factor, which also served as a measure of internal consistency. The value of a Cronbach Alpha should remain above 0.7 to be deemed acceptable (Field, 2009). The values of Factors 1 and 2 were above 0.7, indicating acceptable levels of internal consistency, thus, reliable. Table 4 provides an overview of the exploratory factor analysis for the motivational drivers toward entrepreneurship among Business Management students at a South African HEI.

Table 4: Factor analysis for the motivational drivers toward entrepreneurship

| Item | Factor 1 | Factor 2 | Factor 3 | Factor 4 |
|--|----------|----------|----------|----------|
| I want to become an independent person | 0.858 | | | |
| I want to be the creator of new ideas and innovation | 0.766 | | | |
| I want to act out the capability and skills I was taught at the University | 0.696 | | | |
| I possibly want to explore new market opportunities | 0.665 | | | |
| I have identified a gap in the market | | 0.804 | | |

| Item | Factor 1 | Factor 2 | Factor 3 | Factor 4 |
|--|--------------|--------------|--------------|--------------|
| I already have clients that will support my business | | 0.783 | | |
| I have a serious interest in the subject of entrepreneurship | | 0.589 | | |
| I am afraid of being unemployed | | | 0.763 | |
| I cannot find another job. | | | 0.705 | |
| I potentially want to earn a large salary | | | | 0.883 |
| I want to make my parents proud | | | | 0.717 |
| I want to be my own boss | | | | 0.642 |
| Cronbach's Alpha | 0.819 | 0.731 | 0.321 | 0.679 |
| Inter-Item Correlation Mean | 0.532 | 0.475 | 0.202 | 0.413 |
| Mean Values and Standard Deviation | 13.44 | 8.09 | 4.54 | 10.39 |

Source: Author's own compilation

For the first factor (mean value: 13.44), four items demonstrated similar characteristics according to the statistics of the analyzed data. The items labeled *Greater Business Attainment* included becoming an independent person, being the creator of new ideas, acting out capabilities and skills, and exploring new market opportunities. This was also found in research conducted by Eijdenberg and Masurel (2013), Stefanovic et al. (2010), and Seun et al. (2017).

Factor 2 produced a mean value of 8.09 and included items such as the student having identified a gap in the market, already having clients that will support their business, and having a serious interest in entrepreneurship. This factor was labeled *Availability of Entrepreneurial Opportunities*. This signifies results from Seun et al. (2017) and Stefanovic et al. (2010), which indicated that the availability of entrepreneurial opportunities would significantly impact youth entrepreneurs' readiness to start a business.

Factor 3 (Job Security) yielded a mean value of 4.54, and Factor 4 (Independence) yielded a mean value of 10.39. However, Cronbach's Alpha for these two factors was below the acceptable 0.70 and, therefore, does not prove reliable.

Thus, this specific HEI in the South African context needs to realize that students' perception of greater business attainment plays the most significant role in motivating them to engage in entrepreneurial activity. Therefore, strategies and contingency plans could be developed to equip these students with the necessary skills to generate innovative business ideas, explore and identify feasible and attractive market opportunities, and act on these newly acquired skills to become an independent and successful entrepreneur. Should students gain these skills throughout the course of their undergraduate studies, it might enable them to explore and act on entrepreneurial opportunities well before they graduate. Adding to this, the second most crucial motivational driver is the availability of entrepreneurial opportunities. Should students consider themselves adequately equipped with the skills mentioned above, they will be able to successfully identify gaps in a particular market and build on a client base that will support their business. These students are already registered for degrees in Business Management, where they will gain the skills and knowledge needed to manage a business effectively. However, if they can simultaneously gain and develop practical skills to start their own business, it would contribute to motivating them toward entrepreneurial activity. If they consider this the ultimate result, it will ensure that these students become active entrepreneurs who contribute to economic development and social prosperity within their immediate South African context. Thus, the HEI will succeed in graduating job creators rather than job seekers.

5. RECOMMENDATIONS

This specific HEI needs to reconsider the strategies for creating awareness of entrepreneurship as a career option. This might indirectly influence students' entrepreneurial activity, as they now realise the possibilities yielded by entrepreneurship as a career choice. Furthermore, it is imperative to create ample opportunities for students to purposefully develop the skill to identify viable entrepreneurial opportunities, act on them, and manage the successful implementation of these opportunities within the South African context.

The onus is also on the HEI to ensure that students understand what the 4IR entails and how it impacts the business environment. Considering the immense effect of the 4IR, it would also be critical to assist students in developing the ability to adapt to the changes (such as the use and integration of technology and the speed at which products and services are being offered) based on the impact of the 4IR as entrepreneurs, in order to remain competitive in the marketplace.

6. LIMITATIONS AND FUTURE RESEARCH

This study only focused on students at one HEI in South Africa, where Business Management modules were identified as core modules within the degrees they are registered for. The assumption can be made that these students are already inclined toward business, mainly pursuing a degree within the Faculty of Economic and Management Sciences.

However, conducting this study among students in other faculties and at other HEIs might provide valuable insights regarding whether generic strategies can be developed and implemented with a "one-size-fits-all"-approach or if HEIs should consider customised strategies to develop entrepreneurs based on a field of study and general interests.

7. CONCLUSION

This research aimed to explore the motivational drivers of entrepreneurship among South African Business Management students. Of the four factors identified, only two of these factors were deemed significant and reliable enough to motivate these Business Management students toward becoming active entrepreneurs. These two factors were identified as "Greater Business Attainment" and "Available Entrepreneurial Opportunities," and the results were similar to the finding of previous research studies (Eijdenberg and Masurel 2013; Stefanovic et al. 2010; Seun et al. 2017). This study concludes that it is not enough to focus efforts on assisting students in gaining the necessary knowledge and skill to manage a business successfully, but if the aim is to motivate these students to complete their Business Management degrees towards entrepreneurship as a career choice, education regarding and focus on skills for greater business achievement, as well as exploring and acting on available entrepreneurial opportunities should become deliberate practice not only for the student but also from the perspective of the HEI. Future research opportunities include determining whether the motivational drivers for female and male students differ. Knowledge regarding this will assist the HEI in determining the necessity of developing generic or customized strategic efforts to increase the total entrepreneurial activity among Business Management students.

IMPACT OF REAL EXCHANGE RATE ON ECONOMIC GROWTH IN SOUTH AFRICA

K. Ogujiuba

University of Mpumalanga, Nelspruit, South Africa

W. Gwantsu

University of the Western Cape, Cape Town, South Africa

ABSTRACT

South Africa's Gross Domestic Product (GDP) has been declining over time due to a variety of economic and non-economic variables. Statistics reveal that this drop has been on a consistent downward trend since 2011, following the recovery from the global recession of 2009. However, the links between the exchange rate, inflation, and economic growth are crucial, and any ambiguity or uncertainty in the relationship signals a negative outcome. As a result, this article investigates the impact of the exchange rate on the South African economy. The VECM approach and the Johansen (1995) cointegration technique are used to analyze data from 1990 to 2016. The Johansen test is used to detect whether or not there is long-run cointegration between variables, allowing the Vector Error Correction Model to be implemented (VECM). The variables had a unit root at the level and became stationary at the first difference, according to the data. A 1% depreciation in the Real Exchange Rate (RER) reduces GDP by 14.61 percent over time, according to the data. In the short run, the exchange rate has a negative influence on GDP and inhibits economic growth. A rise in the RER can alter trade surpluses, and a depreciation of the Rand boosts exports in the short run, increasing GDP. Consequently, it will increase foreign reserves, improves employment and output, and conversely improves trade balances. Economic growth increased by approximately **0.261%** caused by a **1%** increase in Real Interest Rate [RIR]. Inflation hurts investment by creating uncertainty; it also affects the balance of payments, making exports more expensive. Our findings suggest that monetary authorities should establish a programme that will follow the prudent monetary policy while simultaneously fostering a favorable climate for economic growth. This will aid in the stabilization of the actual exchange rate and the advancement of South Africa's economy. Because the findings indicate that government expenditure has a significant impact on all variables, it is vital that government spending does not increase at an unsustainable rate if the real exchange rate scale falls in the future. Furthermore, the government's spending should be steady while also paying attention to other economic factors to an equilibrium that does not disrupt importation and other vital economic activities.

Keywords: Cointegration, Economic Growth, Exchange Rate, GDP, South Africa.

1. INTRODUCTION

Before South Africa's democratic transition in 1994, sanctions were applied. South Africa benefited from the sanctions because it was compelled to manufacture goods and services that could not be imported. Domestic markets were supplied by the manufacturing industry. South Africa's economy was closed during the apartheid era, and trade with foreign countries was minimal. Strict procedures were put in place to prevent the inflow of money into the country,

resulting in the country having little money circulating in the economy. The gravity of this consequence compelled South Africa to establish a strong banking system. For the past 25 years, the South African economy has been experiencing slow growth and stagnating prosperity. The challenge of slow growth is that population growth is more than economic growth, which leads the citizen of South Africa to become impoverished over the period. From 1994 to 1999 the first democratic government, the South African economy manifested the massive growth of Foreign Direct Investment (FDI). With the confidence of investors and the sanctions withdrawn, foreign businesses could reinvest. FDI caused a demand increase for domestic currency, which caused an upward shift in exports and international trade as sanctions were lifted. The South African economy increased by an average of 2.5% and inflation averaged 8% per year. Between 1997 and 2010, the South African economy grew at a constant rate thanks to the democratic system. This rate of development, despite its low level, was the outcome of a few macroeconomic policies adopted in South Africa, especially GEAR, ASGISA, and NGP. These macroeconomic policies have played an essential part in sustaining economic development that also actually led to a rise in the South African GDP (Mtonga, 2011; Stan et al. 2007).

However, despite this consistent growth from 1997 to 2010, it has been noted that South Africa's GDP has been growing at a decreasing rate for the previous decade due to various economic and non-economic factors. Statistics indicate this decrease has been on a consistent path from 2011 to date after the resurgence from the recession of 2009, which had a detrimental effect on most economies. Nonetheless, scholars contend that weakening macroeconomic aggregates have a stronger negative push effect on economic growth. As a result, it has become clear that the traditional variables that have been the focus of macroeconomic policies should no longer be the only focus of policymakers. The actual exchange rate problem is expected to influence economic growth. However, in the South African economy, the relationships between the RER, INF, and GDP are important. A depreciated real exchange rate causes aggregate demand to shift from trade to non-traded products, necessitating an increase in interest rates to maintain internal balance (Montiel and Servén, 2008). According to Bernanke (1983), when the exchange rate rises, so do private investments. Furthermore, as the rand falls further, imports become more expensive, capital and worker productivity both diminish, and potential output is reduced. Empirical research on the impact of currency rate fluctuation on exports in South Africa includes Todani and Ganyaupfu (2013); and Edwards and Garlick (2007). According to these studies, exchange rate fluctuation hurts South African exports. In recent years, foreign direct investment (FDI) has been declining, while economic development has been slow.

However, an exchange rate, at which one currency can be traded for another, plays an important role in price stability and economic growth (European Central Bank 2016). The fact that South Africa adopted a flexible exchange rate regime in 2000 means that the economy is facing complications due to currency movements. As reported by the International Monetary Fund (IMF) (2015), despite the seemingly increasing trade in this country during the last decade, net exports have decreased. Furthermore, it is possible that the exchange rate regime adopted in South Africa (Free floating exchange rate in the system) as the cause of this drastic decrease in net exports. These opposing viewpoints have fuelled an ongoing debate about what may be the root cause of South Africa's poor international trade and how low or high exchange rates can be used to improve trade in South Africa.

Only a few studies have attempted to explain the relationship between macroeconomic indicators and economic growth in South Africa. Most studies on economic growth concentrate on a single variable. The argument of a slowly adjusting nominal exchange rate, and high and rising inflation creates a typical problem, which, the central bank manages to preserve price constancy. The ambiguity of overvaluation of RER has a drawback in export improvements and makes possible future growth not to be realized. The appreciation of the domestic currency drives the willingness of foreign investors into a country.

However, other factors determine the exchange rate, and it turns out to make a conducive environment for economic growth. The overall purpose of this article is to investigate the influence of the RER on South Africa's GDP. It's critical to understand how the exchange rate influences South Africa's economic growth. The sanctions that were imposed before 1994 on South Africa have resulted in a little inflow of Foreign Direct Investment, and thus resulted in the slow growth of the economy. Studies reveal that depreciation has a positive effect on economic growth. The concept is commonly known as the traditional view. The view that devaluation positively affects GDP is obvious in that devaluation of the money further increases trade balances, lightens the equilibrium of instalment intricacies, and therefore grows productivity and business (Acar, 2000). The justification for devaluation is that by lowering exchange rates, a country's value intensity on exchanges, which is a part of GDP, improves. The traditional perspective of exchange rates holds that they influence financial development via two key channels: total factor productivity growth and capital aggregation.

The lack of substantial evidence to support the use of either a weak or strong currency as a stimulus for competitive trade has made this a highly contentious issue that needs further investigation. The debate on policy implementation to weaken or strengthen currencies under a floating exchange rate regime has been a grim task in the monetary policy fraternity, in South Africa. There is no clear and comprehensive understanding to date, of whether to advocate a weak or strong currency in developing economies. This debate has divided the Monetary Policy fraternity, especially in emerging or transition economies. Dani (2007) posits that economists around the globe have long discovered that poorly managed exchange rates can be disastrous for economic growth. Furthermore, Habib, Mileva, and Stracca (2016) mention that the persistent debate among various economic agencies and politicians on maintaining a weak or strong currency is fast becoming a major concern that needs immediate consensus, as finding an answer would have far-reaching implications on trade as an instrument of economic growth (Habib et al. 2016). As a result, it is vital to assess the impact of exchange rates on economic growth in developing economies such as South Africa. South Africa is an interesting case study because, despite being one of Africa's most developed economies, the country is plagued with an unstable currency.

2. BRIEF REVIEW OF RELATED LITERATURE

According to Dabla-Norris and Floerkemeier (2006), currency rate fluctuations affect aggregate demand by enhancing international affordability and net exports. In other words, when the Rand falls in value relative to foreign currencies, residents choose domestic goods, enhancing economic performance in the manufacturing sector. The country, on the other hand, sells more and imports less, resulting in a net export surplus. According to Ngandu and Gebreselasie (2006), an increase in exported commodities increases aggregate demand due to the multiplier effect, resulting in a

decline in local manufacturing and unemployment. Depreciation causes inflation, or a general rise in the price level, which results in a decline in the real wage, increased output, and higher unemployment. However, the Total Factor Productivity Growth Channel is criticized for failing to describe how it works in detail, instead relying on assumptions. Furthermore, there is no empirical support for it. Mbaye (2012), for example, stresses the lack of a practical assessment of the impact of exchange rate undervaluation on GDP via the TFP transmission channel. The classic approach's subsequent channel, which appears to be significant, is embraced by policies that link lower exchange rates with higher growth via the impact of local savings rates (Montiel and Serven, 2008). This scenario raises the local saving rate, which in turn raises the capital rate. According to the capital accumulation theory, currency rates influence economic growth by affecting savings. According to this theory, real exchange rate undervaluation boosts growth by increasing the economy's capital stock (Mbaye, 2012). A weakness in this approach is that a depreciated exchange rate tends to boost local saving rates. Depreciation causes people to save more money, which promotes GDP by increasing capital accumulation.

According to Montiel and Serven (2008), there is no specific idea that depicts how the channel effect occurs. However, policymakers understand savings are the transmission channel. Depreciated exchange rates are thought to improve local savings, leading to increased growth through capital accumulation. Tarawalie (2015) used econometric methodologies and quarterly data to investigate the impact of real effective exchange rates on Sierra Leone's economic growth. To determine the causation between the real exchange rate and economic performance, he employed a bivariate Granger causality test. The findings show that the real effective exchange rate has a positive relationship with economic growth, with statistically significant coefficients.

The Balassa-Samuelson hypothesis supports these findings, which show a positive link between real effective exchange rate and GDP. The findings are consistent with those of Ito and Krueger (1999), who discovered a positive relationship between the exchange rate and GDP in Japan and Chile. Ndlela (2013) investigated the effects of real exchange rate misalignment in developing nations, with a particular focus on Zimbabwe's growth. The ARDL cointegration approach was employed in this investigation (autoregressive distributed lag). The ARDL method can be used for variables that are $I(0)$, $I(1)$, or fractionally integrated. The main findings indicate that exchange rate misalignment has a negative and statistically significant impact on growth. Furthermore, the findings support the idea that real exchange rate overvaluation played a key role in Zimbabwe's economic downturn after 2000. Masunda (2010) looked into the impact of misaligned currency rates on Zimbabwean sectoral output. The generalized least squares panel data techniques were used to achieve this, with data from 1980 to 2003 and a sample of Zimbabwean sectors. Mining, manufacturing, and agriculture were among the industries examined in the study. The study discovered that real exchange rate mismatches hurt sectoral production. Even though exchange rate overvaluation has a negative and significant influence on industry output, the study indicated that appreciation has hurt sectoral output. Between 1970 and 1996, McPherson et al. (2010) investigated the direct and indirect links between real and nominal exchange rates and GDP growth in Kenya. Single equation regressions, a system of simultaneous equations, a VAR model test, and cointegration approaches were all used in the research. According to the data, there is no statistically significant direct relationship between changes in exchange rates and GDP. Fiscal, monetary, and foreign aid policies, on the other hand, have an impact on growth. This investigation's findings support the theories outlined in the preceding section. Acar (2014)

explored the impact of currency depreciation on the output growth of emerging countries (LDCs). Panel data were used in the study in 18 different countries. Countries were divided into two groups, each with two regressions. According to the findings, a reduction in the real exchange rate reduces output in the first few years but has an expansionary effect in the following years. Chen (2012) explored the impact of China's real exchange rate on economic growth as well as the convergence of growth rates across provinces. The generalized method of moments (GMM) was used in this investigation. Between 1992 and 2008, a dynamic panel data estimate was used for 28 Chinese regions. The study's findings indicate that actual exchange rate appreciation boosts economic growth in some places. On finite samples, the GMM approach utilized in this work predicts improved performance. The strength of this GMM, according to Bond et al. (2001), is that it can yield constant parameter estimators even when measurement error and endogenous variables are present. The study confirms the Balassa-Samuelson Hypothesis, which argues that the real exchange rate and economic growth are related. On the other hand, his findings do not match Rodrick's (2008). According to the latter, who used data for developing countries encompassing 184 nations and five years for a period of eleven times from 1950-1954 to 2000-2004 for emerging economies, depreciations are expansionary to growth. From 1971 to 2007, Jaussaud and Rey (2009) investigated the long-term determinants of Japanese exports to China and the United States. The ARCH (Autoregressive Conditional Heteroscedasticity) and GARCH (Generalized ARCH) models were used in the study. The findings revealed that actual exchange rate volatility and global demand influence Japanese exports to China and the United States (Gross Domestic Product of the country of destination). The conclusions of this study back the common wisdom that currency depreciation boosts exports and thus GDP, and vice versa. Furthermore, the findings of the study back up Edwards and Garlick's (2007) claim that real exchange rate variations influence trade volumes.

To investigate the Balassa-Samuelson Hypothesis, Ito and Krueger (1999) looked at the relationship between growth rates and real exchange rate fluctuations in (APEC) economies. Economic growth and exchange rate appreciation, both aspects of the Balassa-Samuelson hypothesis, had a beneficial impact on growth in Japan, but not in Chile, according to the study. Malaysia and Thailand have had higher growth rates as a result of the exchange rate depreciation. The conclusions of Jaussaud and Rey (2009), Ito, and Krueger (1999) differ in Japan and Chile, but they coincide in Thailand and Malaysia. Razin and Collins (2007) examined actual exchange rate misalignments and growth for a diverse group of developed and developing countries. According to the research, currency appreciation slows economic growth while depreciation promotes rapid growth. The findings of the study support the conventional theory of exchange rates, which holds that depreciations are associated with rapid growth. Kalyoncu et al. (2008), for example, looked at the long and short-run effects of real exchange rate depreciation on output levels in OECD nations. The outcomes were starkly opposed and, in the end, not the same. In Austria, Poland, and Switzerland, the depreciation of the currency hurt output growth, whereas it had a positive impact on Finland, Sweden, and Germany. Depreciation hurts output in Finland in the short term but has a positive impact on production growth in Switzerland and Hungary.

Vieira and MacDonald (2010) examined the relationship between real exchange rate misalignment and long-run economic development in 100 countries using panel data. The coefficients of the two-step system GMM panel growth models on real exchange misalignment were statistically significant and beneficial in different models and samples, according to the findings. A decline in

the exchange rate improves economic growth in the long run. The coefficients were statistically significant in developing and emerging economies. The impact of exchange rates on economic growth in developed countries has been a source of debate. The impact of real exchange rates on economic progress in industrialized countries has been studied empirically, and the results are mixed. For example, Chen (2012) agreed with the Balassa-Samuelson theory that exchange rates boost economic growth. According to Razin and Collins (1997), exchange overvaluations are associated with slower growth, which is consistent with the traditional understanding of exchange rates. The previous strategy was also backed by Jaussaud and Rey (2009), who discovered that as the Japanese yen appreciated, so did Japanese exports to China and the US. As a result, growth was hampered.

Greater real exchange rate depreciation, according to Vieira and MacDonald (2010), is advantageous to future growth. Despite the lack of agreement, some research has linked currency overvaluations to slower economic development. Aguirre and Calderon (2005) explored the growth consequences of RER misalignments and their instability. Actual exchange rate departures from equilibrium were used to calculate real exchange rate misalignments. Real exchange misalignments diminish growth, but the effects are non-linear; for example, growth declines are greater in direct proportion to size misalignments. The study covered the period 1965-2003 for 60 nations using panel and time series cointegration methods. According to Bond et al. (2001), an increase in the exchange rate boosts economic growth and verifies the Balassa-Samuelson Hypothesis, which argues that the real exchange rate and economic growth are linked. Rodrick's (2008) results, on the other hand, aren't usually constant. The latter discovered that depreciations are expansionary for growth using data for emerging countries containing 184 nations and five years for a span of eleven times from 1950-1954 to 2000-2004. According to the capital accumulation theory, exchange rates influence economic growth by changing savings. There is no unique theory that illustrates how the channel effect happens, according to Montiel and Servén (2008). Policymakers, on the other hand, are fully aware that savings are the transmission channel. Nonetheless, exchange rate depreciation is expected to increase local savings rates, which enhances GDP by increasing capital accumulation.

There are two sources of capital accumulation represented in the capital accumulation channel. Tarawalie (2015) investigated the effects of real effective exchange rates on Sierra Leone's economic growth using econometric approaches and quarterly data. To determine the causation between the real exchange rate and financial performance, he utilized a bivariate Granger causality test. The findings reveal that the real effective exchange rate has a statistically significant positive link with economic growth. These findings support the Balassa-Samuelson hypothesis, revealing a positive relationship between the real effective exchange rate and GDP. Ito and Krueger (1999) observed a positive association between the exchange rate and GDP in Japan and Chile, and their findings are similar. As a result of the currency depreciation, global and domestic demand for exported goods will rise, thereby, increasing exports. According to the theory that depreciation has a positive impact on GDP (Acar, 2000), depreciation improves trade balances, reduces the balance of payments concerns, and hence boosts productivity and employment. Tarawalie (2015) used econometric methodologies and quarterly data to explore the effects of real effective exchange rates on Sierra Leone's economic growth. He examined the relationship between the real exchange rate and economic performance using a bivariate Granger causality test. The findings reveal that the real effective exchange rate and economic growth have a statistically significant positive

association. This finding is supported by the Balassa-Samuelson (2013) hypothesis evaluation, which demonstrates a positive relationship between the real effective exchange rate and GDP.

3. DATA AND METHODS

3.1 Research Technique

The VECM method and the Johansen (1995) cointegration technique are used in the analysis. To accomplish this, the unit root was deployed to see whether data sets are stationary. A VECM is used for non-stationary series that are known to be cointegrated. According to Brooks (2008), the VECM specification includes cointegration relations, which limit endogenous variables' long-run behavior to converge to their co-integrating connections while allowing for short-run adjustment dynamics. According to Brooks (2008), the cointegration component is also known as the correction term because the departure from long-run equilibrium is gradually corrected through a series of approximated partial short-run corrections. As a result, the vector error correction model (VECM) specification requires the presence of a cointegration connection (s). The Engle-Granger approach, which is based on residuals, and the Johansen and Julius (1990) strategy, which is based on a maximum likelihood estimate on a VAR system, are two approaches for testing for cointegration. Simultaneous equation bias, the inability to test hypotheses about the genuine cointegration connection, and a lack of power in the unit root test are all weaknesses in the Engle-Granger approach (Brooks, 2008). Because the Engle-Granger method has flaws, this study applies Johansen's vector error correction modeling (VECM) (1991). The purpose of this method is to estimate the long- and short-run determinants of a model's dependent variable using determined probability estimation in a vector error correction (VEC) model. This approach also provides the speed of adjustment coefficient, which quantifies how quickly the Gross Domestic Product rebounds to equilibrium after a short-term shock to the system (Gujarati, 2004). We may interpret long-term and short-term equations using VECM. However, the number of co-integrating relationships must be determined. The advantage of using VECM over VAR is that the generated VAR has more efficient coefficient estimates. The VECM also looks for the presence of a long-run link between variables. The primary advantage of VECM is that it interprets long-term and short-term equations well. In theory, VECM is nothing more than a representation of cointegrated VAR. Granger's representation theorem is responsible for this representation. As a result, if you have a cointegrated VAR, it has VECM representation and vice versa.

3.2 Model Specification

The model in this study is based on the methodology by Azid et al. (2005) as they examined the impact of exchange rate volatility on growth and economic performance, in a case study of Pakistan from 1973-to 2003. The model was estimated using Vector Auto-Regression (VAR). The equation for this model was specified as follows.

$$GDP(Y) = \beta_0 + \beta_1 RER + \beta_2 EX + \beta_3 IM + \beta_4 RM \dots\dots\dots (1)$$

Where:

β_0 , = constant term

$\beta_1, \beta_2, \beta_3, \beta_4$ = are the coefficient of the parameters

RER= Real exchange rate

EX= Exports

IM = Imports

RM= Real Money Supply

The study's goal is to find out how real exchange rate performance affects economic growth (GDP). Economic growth (GDP) is the dependent variable in this study, which is explained by changes in the real exchange rate (RER), real interest rate (RIR), and trade openness (TRD). The model is specified as follows

$$GDP = \beta_0 + \beta_1 RER + \beta_2 RIR + \beta_3 EXP + \beta_4 IMP + \varepsilon_t \dots \dots \dots (2)$$

Where:

- β_0 =Constant term
- $\beta_1 - \beta_4$ =Slope of the parameters
- GDP* = National Gross Domestic Product
- RER* =Real Exchange Rate
- RIR* =Real Interest Rates
- TRD* =Trade openness
- INF* =Inflation
- ε =error term
- t* =time series

The empirical model is estimated with the econometric software E-views 9.5

Table 1: Definition of variables and Data sources

| S/N | Variables | Definitions |
|-----|-------------------------------|--|
| 1. | Gross Domestic Product | South Africa's Gross Domestic Product is measured in billions of Rands, and this illustrates the percentage change in GDP from the preceding measurement cycle. |
| 2. | Real Exchange Rate | RER is the nominal exchange rate that takes inflation differences between countries into account and uses as a competitiveness indicator in a country's foreign commerce. |
| 3. | Real Interest Rates | The real interest rate is the nominal interest rate adjusted for predicted inflation, and it measures the difference between the nominal and expected interest rate increases. |
| 4. | Trade Openness | The ratio of imports and exports to gross domestic product is known as trade openness. |
| 5. | Inflation | Inflation is a general increase in the prices of goods and services in an economy. When the general price level rises, each unit of currency buys fewer goods and services; consequently, inflation corresponds to a reduction in the purchasing power of money. |

Justification of Variables in the Model

The interest rate affects inflation indirectly through domestic demand for goods and services, as well as through its effect on the exchange rate. Saving becomes less profitable for families when interest rates fall, and they will thus increase their consumption now rather than later. Furthermore, inflation affects every sector of the economy, including consumer spending, corporate investment, and labor rates, as well as government programs, tax policies, and interest rates. Inflation is important for investors to understand because it has the potential to reduce the value of investment returns. Aside from interest rates and inflation, the currency exchange rate is one of the most important drivers of a country's relative economic health. Exchange rates are critical to a country's trade volume, which is critical to almost every free market economy on the planet. Furthermore, trade openness has been shown to potentially boost long-term economic growth by providing

access to goods and services, increasing resource allocation efficiency, and increasing total factor productivity through technological diffusion and knowledge dissemination.

3.3 Preliminary Tests

Stationarity

The quality of a process in which the statistical characteristics (mean and standard deviation) remain constant across time is known as stationarity. The distance or gap between the times, not the actual time at which the covariance is computed, determines the covariance values between the two periods (Gujarati, 2004). The autocorrelation function (ACF) of a stationarity process is solely dependent on lag and does not modify the time in which the service was generated. Both the dependent and independent variables must be stationary, and the errors must have a zero mean and bounded variance, according to the traditional regression assumption (Brooks, 2008).

The following are some of the reasons why data should be checked for stationarity:

- First, series can have a big impact on its behavior and qualities; second, it can cause a misleading regression problem, which happens when two variables are trending in the same direction over time.
- A regression of one variable on the other could have a high R squared even though the two variables are unrelated.
- Third, the traditional assumption of asymptotic analysis will be incorrect. As a result, the conventional t-ratio will not follow a t-distribution, and the F-statistic will not follow an F-distribution, rendering a regression parameter hypothesis test invalid (Brook, 2008).

Augmented Dickey-Fuller (ADF) Test

The Dickey-Fuller test is used to determine the order of integration (Gujarati, 2004). A unit root test can be used to determine whether a time series is stationary. The most commonly used unit root tests are the Dickey-Fuller (DF) and Augmented Dickey-Fuller (ADF). ADF theory aimed to test the hypothesis that $\phi=1$ in

$$Y_t = \phi (y_{t-1}) + \mu_t \dots\dots\dots 4.3$$

Thus, the assumption is formulated:

H₀: Series contains a unit root

H₁: Series is stationary

The rejection of the null hypothesis under these tests means that the series does not have a unit root problem. The standard ADF test estimates

$$Y_t = \beta_1 + \beta_2 \Delta Y_{t-1} + \mu_t \dots\dots\dots 4.4$$

Where μ_t is the relevant time series, Δ is the first difference operator, t is a linear trend, and ϵ_t is the error term. Normality, constant error variance, and independent error terms should all be met by the error term. Gujarati (2004) claims that if the error terms in equation (4.4) are not separated, the Dickey-Fuller tests will be biased. If there is autocorrelation in the regression of the dependent variable (y_t), the Dickey-Fuller test is valid only if (t) is assumed and not autocorrelated. As a result, the test would be 'oversized,' meaning that its real size would be larger than the nominal size. The solution to this shortfall is to use the ADF. The alternative model in the ADF case can be written as:

$$\Delta y_t = \beta_1 + \beta_2 t + \delta y_{t-1} + \sum_{i=1}^m \alpha_i \Delta y_{t-i} + u_t \dots \dots \dots 4.5$$

Where there is a pure white noise error term and where $\Delta y_{(t-1)} = (y_{(t-1)} - y_{(t-2)})$, $y_{(t-2)} = (y_{(t-2)} - y_{(t-3)})$, etc. The number of lagged difference terms to include is often set empirically, according to Gujarati (2004); the goal is to include enough terms so that the error term in (4.5) is serially uncorrelated. The test is whether $\delta = 0$ in both ADF and DF, and the ADF test follow the same asymptotic distribution as the DF statistic, allowing for the usage of the same critical values. If the estimated value is greater than the significant value, the null hypothesis that the series has a unit root is rejected, suggesting that the series is stationary. A crucial assumption of the DF test, according to Gujarati (2004), is that the error terms (t) are distributed independently and identically. The ADF test extends the DF test to account for any serial correlation in the error terms by adding the lagged difference terms of the regression (t). As with any other unit root test, the Dickey-Fuller test contains flaws.

Nonetheless, the DF test has a fault in that it disregards the potential of error term autocorrelation (t). According to Clemente et al. (1998), a well-known problem of the Dickey-Fuller style unit root test with I(1) as the null hypothesis is the risk of misinterpreting structural breaks in the series as evidence of non-stationarity. The Dickey-Fuller test also has a fault, according to Blungmart (2000), in that it does not account for possible autocorrelation in the error process (t). The OLS coefficient estimates will be wasteful if t is auto-correlated, and t-ratios will be skewed. In response to the aforementioned shortcomings, the Augmented Dickey-Fuller test was devised, and it is now preferred over the Dickey-Fuller test.

Cointegration test (Johansen and Julius technique)

Johansen and Julius (1990) devised a technique based on the maximum likelihood estimate for a VAR system. This method is used to find a long-run equilibrium connection and has the benefit of identifying all cointegration vectors inside a given set of variables. Testing the sequence of integration of the variables under consideration is required when using the Johansen procedure. All variables should be integrated in the same order before completing the cointegration test. Johansen and Juselius propose critical values for the two statistics (1990). The distribution of the test statistic is non-standard, and the significance is high. The procedure is specified as follows with a Vector autoregressive (VAR) model representation of order k:

$$y_t = \Pi_1 Y_{t-1} + \Pi_2 Y_{t-2} + \dots + \Pi_k Y_{t-k} + u_t$$

Where y_t is a -vector of non-stationary I (1) variables, kt is a D-vector of deterministic variables and u_t is a vector of innovations. To practice the Johansen test, the VAR (4.1) above needs to be turned into a VECM specification (Brooks, 2008). We may rewrite this VAR

The VAR model of equation 4.1 above is transformed into a VECM of the following form:

$$\Delta y_t = \mu + \pi_k Y_{t-k} + \sum_{i=0}^q \Gamma_i \Delta Y_{t=i} + \mu_t$$

Where $q=k-1$, ΔY_t is all I (0), Γ is n x n coefficient matrices which represent the short-run coefficients. π is the matrix whose rank r determines the number of cointegration vectors among the variables. The Johansen test is based on the examination of the π matrices. If $r=0$ then there are no cointegration vectors. According to (Gujarati, 2004) if for instance π has a reduced rank ($r \leq (n-1)$), this implies that it can be decomposed as follows:

$$\Pi = \alpha \beta$$

Where α is an $n \times r$ matrices of error correction or speed of adjustment parameters and β , is the long-run coefficients. Estimates of β are found by solving the eigenvalue problem so that the eigenvectors corresponding to the r largest eigenvalues form the estimated β matrix. The size of the eigenvalues shows a measure of how high the correlation between the cointegration relationship and the stationary part of the model is. The next step is to begin how many cointegration vectors exist for each of the relationships. Two test statistics are employed, the λ max statistic and the λ trace statistic. The λ max statistic is of the form:

$$\lambda_{\max}(r+1) = -T \ln(\lambda_{(r+1)})$$

$$\text{and } \lambda_{\text{trace}}(r) = -T \sum_{i=r+1}^g (\ln(1-\lambda_i))$$

Where r is the number of cointegration vectors under the null hypothesis and λ_i is the estimated value for the i^{th} ordered eigenvalue from the matrix. Intuitively, the larger is λ_i , the larger and more negative will be $\ln(1-\lambda_i)$, and hence the larger will be the test statistic. Each eigenvalue will have its cointegration vector, which will be made up of eigenvectors. A significant cointegration vector is indicated by a non-zero eigenvalue. λ_{\max} conducts separate tests on each eigenvalue and has as its null hypothesis that the number of cointegration vectors is r against an alternative of $r+1$. λ_{trace} is a joint test where the null is that the number of cointegration vectors is less than or equal to r against an unspecified or general alternative that there are more than r . It starts with p eigenvalues, and then successively the largest is removed. $\lambda_{\text{trace}} = 0$ when all the $\lambda_i = 0$, for $i = 1, \dots, g$.

4 RESULTS AND DISCUSSION

For stationarity, all the deterministic trend assumptions of Constant, Constant with the trend, and None were verified. Because the value of t-statistics is smaller (less detrimental) than the crucial Mackinnon values for all deterministic trend assumptions, the variables have a unit root in levels, as indicated in the table below. As a result, the unit root null hypothesis is accepted. After first differencing, the t-statistics become more significant (more negatives) than the crucial Mackinnon values for all deterministic trend assumptions. The null hypotheses including unit roots are thus rejected, but the alternative hypothesis involving no unit root in the series is supported.

Table 2: Stationarity Test Results

| Augmented Dickey-Fuller | | | | | |
|-------------------------|----|----------|------------------|---------|----------------------|
| Variables | | Constant | Constant & trend | None | Order of integration |
| LGDP | | -0.0372 | -0.1789 | -1.3734 | I(0) |
| LXR | | -0.9990 | -2.2594 | -2.2594 | I(0) |

**represents a stationarity variable at a 5% level of significance

Pair-wise correlation

In this study, the Pair-wise correlation Matrix is utilized to discover the exact link between the six variables. The table shows the results of the pair-wise correlation matrix.

Table 3: Pair-wise Correlation Results

| Variables | DLGDP | DLINF | DLRIR | DLTRD | DLXR |
|--------------|-----------|-----------|-----------|-----------|-----------|
| DLGDP | 1.000000 | -0.153602 | -0.161320 | 0.061631 | -0.054803 |
| DLINF | -0.153602 | 1.000000 | 0.085471 | 0.301994 | 0.305747 |

All components are positively related to the dependent variable DLGDP, according to the pair-wise correlation statistics presented above. The connection between DLTRD and DLGDP is stronger than the others. The fact that both variables have a positive association lends credence to the theoretical framework. According to the theory, increasing trade openness should promote economic growth. According to theoretical assumptions (Appleyard and Field, 2005), high-interest rates and real exchange rates generate a negative relationship between the variables by discouraging investment and exports, resulting in lower economic growth. The finding also demonstrates that multicollinearity among variables is not an issue. This supports the claim that all variables correlate with DLGDP and that no single variable corresponds to all variables, implying that the multicollinearity problem is unlikely. In this regard, DLGDP agrees with the proposed explanatory elements.

Cointegration

Cointegration indicates that the variables have a long-run relationship. When variables are cointegrated, they integrate in the same order; however, when at least one or more variables are linearly combined, they integrate into order I. (0). The Johansen test must be used to establish an appropriate lag-order criterion. It eliminates serial correlation from the residuals and identifies the deterministic trend assumption in the VAR model. Table 4 shows how different information factors influence lag-order selection. The Johansen (Maximum likelihood) cointegration technique is used to determine the presence of cointegration and the number of cointegration vectors (Johansen 1988, 1991). The method comprises determining the optimal lag length and choosing the deterministic assumption that the Johansen test requires. The table below shows the lag duration requirements obtained from the unrestricted VAR. The appropriate lag time should result in residuals that are uncorrelated and homoscedastic. To resolve the differences, sophisticated diagnostics were used to consider all lags as well as lag duration. Lag 2 is the ideal lag for this data collection. As a result, the Johansen cointegration test is done with two delays for the VAR and a constant in the series.

Table 4: Lag Order Selection Criterion

| Lag | VAR Lag Order Selection Criteria | | | | | |
|-----|----------------------------------|-----------|-----------|------------|------------|------------|
| | LogL | LR | FPE | AIC | SC | HQ |
| 0 | -96.44118 | NA | 7.93e-06 | 2.444366 | 2.590079 | 2.502905 |
| 1 | 480.7783 | 1070.986 | 1.32e-11 | -10.86213 | -9.987849 | -10.51089 |
| 2 | 554.4989 | 127.9007* | 4.11e-12* | -12.03612* | -10.43327* | -11.39218* |
| 3 | 560.1946 | 9.195507 | 6.65e-12 | -11.57095 | -9.239541 | -10.63432 |
| 4 | 568.3668 | 12.20912 | 1.03e-11 | -11.16547 | -8.105487 | -9.936137 |

* indicates lag order selected by the criterion
 LR: sequential modified LR test statistic (each test at 5% level)
 FPE: Final prediction error
 AIC: Akaike information criterion
 SC: Schwarz information criterion
 HQ: Hannan-Quinn information criterion

The results of the Johansen cointegration technique are reported in the table below.

Table 5: Cointegration rank test results

| Hypothesized No. of CE(s) | Eigenvalue | Trace Statistic | 0.05 Critical Value | Prob.** |
|---------------------------|------------|-----------------|---------------------|---------|
| None * | 0.554569 | 120.3796 | 69.81889 | 0.0000 |
| At most 1 * | 0.373862 | 54.87395 | 47.85613 | 0.0095 |
| At most 2 | 0.151579 | 16.95101 | 29.79707 | 0.6437 |
| At most 3 | 0.041610 | 3.636411 | 15.49471 | 0.9307 |
| At most 4 | 0.002391 | 0.193880 | 3.841466 | 0.6597 |

According to Table 5, the findings of the trace test indicate that cointegrated equations exist at a 5% level of significance. The null hypothesis of no cointegrating vectors is rejected since the trace test statistics of 120.37 are greater than the threshold of 69.82 at a level of significance of 5%. Because the trace test value of roughly 54.87 is greater than the needed 47.85 at the 5% level of significance, the null hypothesis that there is only one cointegration vector can be rejected. Because the trace statistic of roughly 16.95 is less than the crucial value of 29.78 at 5% significance, the null hypothesis that there are only two cointegration vectors can be accepted, as can the null hypothesis that there are only three. Vector Error Correction Model (VECM)

The results show that there is a cointegration equation, which implies that a VECM model can be used.

Long run and short run cointegration equation

In an econometric analysis, time series variables that are cointegrated with error-correlation representatives must reflect a short-run adjustments mechanism. The following section shows the relationship between short-run and long-run dynamics, which is the cointegration vector.

Table 6: Long-run and Short-run Cointegration Equation

| Short-run Analysis | | | |
|--------------------|-------------|----------------|-------------|
| Variables | Coefficient | Standard error | t-statistic |
| Constant | -0.030535 | - | - |
| DLGDP | 1.000000 | - | - |
| DLINF | -1.424798 | 0.68517 | -2.07948 |
| DLRIR | -2.120526 | 0.64942 | -3.26526 |
| DLXR | -3.796998 | 1.65710 | -2.29135 |

Table 6 shows the long-run influence of real exchange rates XR, INF, RIR, and TRD on GDP. The cointegration vector reveals that DLGDP, real exchange rate, real interest rate, inflation, and trade openness have a stable long-run connection. The real exchange rate exhibits a substantial negative long-run connection with the dependent variable GDP, as seen in Table 6. All other variables were also significant and had the correct sign. The coefficient of DLGDP is 0.8626 in the table above,

indicating that the rate of adjustment is around 86.26 percent. This means that if a divergence from equilibrium occurs, only 86.26 percent of the error is rectified in quarter one as the variable approaches equilibrium. This means that whenever there is a disturbance, there is tremendous pressure on economic growth to restore long-run equilibrium. With an absolute t-value of roughly -6.180, this rate of adjustment is statistically significant. Economic growth's rapid adjustment may indicate that the model is well-fitted.

According to the data, a 1% increase in the real exchange rate leads GDP to decline by 14.61 percent in the long run, which is a significant effect. This is confirmed by the analogy that an increase in the currency rate or a depreciation of the rand against the dollar will affect the supply and demand of imported goods. Table 6 shows that the exchange rate hurts economic growth in the short term. A 1% increase in the real exchange rate results in a 3.79 percent reduction in economic growth. An increase in the real exchange rate affects the trade surplus, while a depreciation of the rand reduces exports in the short run, lowering GDP. In the long run, a 1% increase in RIR reduces economic growth by about 0.261 percent. In the long run, a low real interest rate will attract foreign direct investment, particularly portfolio investments that will help to strengthen South Africa's balance of payments accounts, so boosting economic growth. In the short run, real interest rates hurt growth. RIR increases reduce growth by about 21.20 percent, which is statistically significant. An increase in real interest rates is expected to result in a decrease in economic growth due to the inverse relationship between investments and interest rates. In the short run, a 1% increase in TRD slows economic growth by 19.15 percent, according to the data. On the other hand, trade openness has a long-term positive and significant impact on economic growth. Exports of higher grades increased by about 26.27 percent.

High-quality exports, according to Hausmann et al., (2007), increase economic growth. A 1% increase in inflation, according to the research, will influence economic growth. A drop in inflation is expected to enhance GDP by 14.24 percent in the short term and 0.6 percent in the long run. This is reinforced by the fact that lower prices increase purchasing power, which aids economic growth. Furthermore, inflationary pressures influence investment because of uncertainty, as well as the balance of payments since exports become more expensive. However, fiscal policy can be used more effectively to stabilize the domestic economy following a price shock. It also indicates that government expenditure should be allocated efficiently to successfully regulate local pricing (CPI) and balance payment difficulties, such as import levels.

Diagnostic Test Results

The economic growth model has been thoroughly tested. Normality, serial correlation, autoregressive conditional heteroscedasticity, and stability were all examined in the model. Diagnostic checks were performed on the model to ensure that the parameter evaluation of the model's outputs was proper. Any issues with the estimated model's residuals will render the model inefficient, and the estimated parameters will be skewed. The null hypothesis states that there is no serial correlation in the LM test, no normalcy in the Jarque-Bera test, and no heteroscedasticity in the Jarque-Bera test.

Table 7: Diagnostic Test Results

| Test | Null hypothesis | t-statistic | Probability |
|--------------------------|-----------------------------------|-------------|-------------|
| Lagrange multiplier (LM) | No serial correlation | 24.15221 | 0.5106 |
| White (CH-sq) | No conditional heteroscedasticity | 489.3051 | 0.3745 |
| Residual Normality | Normal distribution | 58.45 | 0.0000 |

Heteroscedasticity

The white test with no cross-terms was employed to test for heteroscedasticity in Table 7, providing a Ch-sq of 489.3051 at a probability of 0.3745, suggesting that the null hypothesis of no heteroscedasticity was accepted. According to the findings, the residuals are homoscedastic.

Langrage Multiplier (LM) test

In Table 7, the LM statistic for serial correlation was 24.15221 with a probability of 0.5106, indicating that the null hypothesis could not be rejected.

Normality test

To determine residual normality, the Jarque-Bera (J-B) test was utilized. Based on the results of table 7, the Jarque-Bera statistics of 58.45 with a probability of 0.0000 indicate that the null hypothesis is accepted at the 5% level. The residuals appear to be regularly distributed as a result.

Impulse Response Analysis

The generalized impulse response functions represent the dependent variable's reaction to shocks to each of the variables in the VECM. Each equation's inaccuracy is assigned a unit shock, and the effects on the VECM system are tracked for 15 years. Our primary purpose, however, is to analyze the influence of the exchange rate on the South African economy. Only the GDP, the dependent variable, is evaluated for responsiveness. Because this study focuses on the impact of real exchange rate volatility on economic growth, only the responses of economic growth to the real exchange rate and the responses of economic growth to explanatory variables are provided. These impulse response functions show the dynamic response of economic development to a one-period standard deviation shock to the system's innovations, as well as the directions and durability of the responses across ten quarters. The impulse response functions mainly follow the expected pattern and back up the conclusions of the short-run relationship analysis.

All the variables are subjected to strong shocks, but they are brief. Except for the fifth and eighth quarters, actual exchange rates begin to decline in the first quarter. Except for the fourth and eighth quarters, gross inflation was positive in the first quarter. However, there is a favourable correlation between economic advances in all other quarters. The real exchange rate will be positive from the first to the tenth quarters, except the third and eighth quarters, which will be negative, and the interest rate will be negative from the first to the tenth quarters, except the fourth and fifth quarters, which will be positive.

Variance Decomposition Analysis

It determines how much volatility in a variable's forecast error may be explained by innovations and other factors. Using variance decompositions on the VECM, the ratio of movements in the dependent variables attributed to their "own" shocks vs. shocks to the other variables is computed (Brooks, 2008). According to Brooks, the majority of a VAR's forecast error variation is accounted for by its series of shocks. The same factorization approach and information are used in the variance decompositions as in the estimate of impulse responses. The variance decomposition

technique is used to determine the relative importance of the dependent variable in explaining variation in the explanatory factors. Variance decomposition is a tool for determining the relative importance of actual exchange rate shocks in explaining economic fluctuations. Table 8 presents the variance decomposition results over 10 quarters.

Table 8: Variance Decomposition of GDP

| Periods | S. E | GDP | INFL | TRD | RER | RIR |
|---------|----------|----------|----------|----------|----------|----------|
| 1 | 0.010564 | 100.0000 | 0.000000 | 0.000000 | 0.000000 | 0.000000 |
| 2 | 0.015234 | 96.36342 | 1.783953 | 0.475691 | 0.058925 | 1.318008 |
| 3 | 0.016030 | 87.27163 | 1.973813 | 7.544311 | 0.053583 | 3.156667 |
| 4 | 0.016429 | 83.08426 | 1.977719 | 7.720680 | 0.661651 | 6.555695 |
| 5 | 0.018952 | 84.84720 | 1.868866 | 6.618728 | 1.069738 | 5.595470 |
| 6 | 0.021611 | 84.23713 | 3.291618 | 5.151754 | 1.057605 | 6.261891 |
| 7 | 0.022032 | 81.25870 | 3.813547 | 7.391321 | 1.170221 | 6.366212 |
| 8 | 0.022276 | 79.49986 | 3.922246 | 8.158348 | 1.500454 | 6.919093 |
| 9 | 0.024155 | 81.90014 | 3.626512 | 7.102958 | 1.421198 | 5.949192 |
| 10 | 0.026100 | 82.82777 | 3.880602 | 6.088053 | 1.245798 | 5.957773 |

The study allows for a ten-quarter variance decomposition to identify the effects when the causes can have a long-term impact on economic growth. According to Brooks (2008), their invention in the first-year accounts for all GDP discrepancies (2008). For the upcoming fifth quarter, GDP accounts for around 85 percent of the difference in prediction error variance, while the remaining elements account for approximately 15 percent. Inflation accounted for 1.87 percent of total expenditure, trade for 6.62 percent, RER for 1.07 percent, and RIR for 5.60 percent. However, after ten quarters, economic growth accounted for roughly 83 percent of the difference, with other factors accounting for the remaining 17 percent. The influence of the exchange rate increased by approximately 3.88 percent, whereas INF decreased to around 6.09 percent. RER increased to 1.25 percent, and RIR increased to 5.96 percent. Similar to the findings of the impulse response analysis, all of the components have a significant short-term impact on economic growth. Most of the fluctuations are explained by economic growth, followed by inflation and real interest rates. Furthermore, the real exchange rate does not indicate anything about economic development swings.

5. CONCLUSION AND POLICY RECOMMENDATIONS

The primary goal of the study was to examine the influence of real exchange rate performance on economic development between 1990 and 2016 using a concrete approach and a review of relevant literature. In the results, the stationary test demonstrates that the variables have a unit root at the level and that the variables become stationary at the first difference. The Johansen-Juselius model required the usage of the VECM. The model demonstrates that the real exchange rate influences both long-term and short-term economic growth. The residuals were subjected to diagnostic tests. To test the responsiveness of the dependent variable, the impulse response was used to assess the shocks to each of the other variables. Although the factors were substantial, they did not all produce shocks in other variables and were not persistent. The variance decomposition sought to identify the causes responsible for the bulk of the changes in the dependent variable. Most of its movements are explained by GDP, followed by the exchange rate. The null hypothesis in this study was that the real exchange rate hurt South Africa's economic growth. Based on the regression results, the null hypothesis is accepted. Monetary policy and fiscal policy are the two policy options for dealing with the economy's real exchange rate. The SARB uses interest rates to impact

monetary policy through inflation targeting (Repo). The flexible inflation-targeting system is overseen by the Monetary Policy Committee (MPC), which also conducts and implements monetary policy. It enables the regulation of inflation within a specific range. Exchange rate shocks often cause inflationary pressures. In times of rising inflation, the central bank's action may be laudable. However, depending entirely on monetary policy to manage inflation during goods price shocks may have unintended consequences, such as rand depreciation, which increases the cost of importing commodities. Government spending should not be increased so quickly that it becomes unsustainable if the real exchange rate falls. Because an exchange rate shock could come at any time while the government spends more on other operations, the government's spending and other economic activities must be consistent to maintain a balance that does not disrupt importation or other strategic economic activity. A scenario like this would have a significant economic impact since the government would be forced to prioritize goods imports to keep the economy afloat. Because of improved speculative conditions as a result of WTO expansion, it appears reasonable to expect that the country will need to develop its primary businesses and increase the intensity of non-energy segments by attracting FDI from other countries. In addition to monetary and fiscal policy initiatives, regional integration must be promoted.

Although the foundations and assumptions of the various theories examined in this study differed, the basic premise in most of them was that policymakers might use real exchange rates as a tool to attain high levels of economic growth over time rather than in the short term. The study was limited to quarterly data from 1990 to 2016 and did not include any data before South Africa implements an inflation-targeting program. Future research should evaluate the impact of the exchange rate before and after South Africa implements its inflation-targeting policy.

VALIDITY OF DEBT ACCUMULATION FOR ECONOMIC AND SUSTAINABLE DEVELOPMENT: EVIDENCE FROM NIGERIA

K. Ogujiuba

University of Mpumalanga, Nelspruit, South Africa

E. Olamide

University of Mpumalanga, Nelspruit, South Africa

ABSTRACT

This research investigates the impact of government debt on economic development in Nigeria between 2000 and 2020. The link and degree of significance were determined using data on economic development proxies. Because it allows for more than one co-integrating association among the variables, the Johansen maximum likelihood regression strategy was used. The correlation between debt accumulation, and economic and sustainable development has received extensive consideration in development literature. While some analysts support the debt accumulation and economic transformation nexus, others maintained that the bond between debt accumulation and economic transformation is not enduring along a country's growth path. The findings imply that Gross Domestic Product (GDP) per capita and total debt profile has a favorable relationship. The literacy rate and total debt and population of the population beneath the poverty line and total debt were not statistically significant within the study period. During the study period, debt hurt the country's economic and long-term growth. The findings also instruct that the Nigerian government explores the causes of public debt not contributing to the country's GDP per capita to identify and correct bottlenecks. This study suggests that transformations aimed at improving policy and institutional performance, particularly in the areas of economics and debt management, be examined. Further, stronger fiscal positions and better financing arrangements from creditors were equally advocated for.

Keywords: Debt, development, economic, GDP Nigeria

1. INTRODUCTION

In the development literature, the relationship between debt accumulation and economic and sustainable development has garnered a lot of attention. Although available pieces of evidence linked the nexus between debt accumulation with economic growth, debate on how much to borrow and how to manage such debt coupled with the long-term repercussions of such debt still rages (Fosu, 2007; Minea and Parent, 2012; Senadza et al., 2018; Omodero et al., 2020; Ekor et al., 2021; Yusuf & Mohd, 2021). According to research, the United States of America is the world's largest debtor country, however, despite the global economic downturn, the country has seen significant economic growth and success (Blakely & Leigh, 2009). Nevertheless, the negative effect of debt maintenance on economic growth especially in African countries is attributable to the decline of public spending because of debt-induced liquidity restraints (Taylor, 1993; Ndulu and O'Connell, 2021). The budget could be swayed away from public investment due to liquidity constraints inferred from debt-servicing conditions. This is important to consider because government spending is expected to be a major driver of economic activity in many areas (Fosu,

2007; Festus and Saibu, 2019; Yusuf and Mohd, 2021). However, Nigeria has been exploiting both external and domestic debt to the extent that the debt servicing is leading to a welfare loss for the citizenry (Ohiomu 2020). Adedoyin et al. (2016) and Yusuf and Mohd (2021) argued that 'crowding out and the 'debt overhang' influence of debt maintenance appears to describe, to a large extent, the Nigerian economy's low level of investment. This has constituted a serious infrastructural gap in all tiers of government as it interrupts the steady flow of capital to the public treasury. Regardless of the expanding nature of the debt stock, particularly from 2015 to the year 2020, Nigeria's economic progress is not encouraging, especially when considering essential aspects such as job creation, poverty reduction, and other socio-economic difficulties the country faces (Ekor et al., 2021).

The "debt overhang" effect lowers economic performance by leading to tax disincentives and macroeconomic instability (Abdullahi et al., 2016; Shkolnyk and Koilo, 2018). Effects of macroeconomic instability include rising fiscal deficits, uncertainty resulting from unconventional financing, potential monetary expansion, depreciation of currencies, and anticipated inflation (Ohiomu, 2020; Yusuf & Mohd 2021). "The burden connected with debt service in Nigeria hampered and aggravated her rapid economic growth and social issues," claims Ohiomu (2020) in his debt overhang hypothesis. Because of a lack of funds, major institutions' ability to provide services aimed at improving the living conditions of the poor has been limited. The government appears to have hampered private sector investment and growth by reducing social and economic infrastructure spending due to market failures. Because public investment accounts for a large portion of total investment in the country, total investment has decreased and welfare loss has increased.

This paper was motivated by the observed disparity between the volume of the debt stock and economic realities, such that human development indicators in Nigeria continue to show negative signs in the face of unabated socioeconomic challenges. Nigeria has continued to accumulate debt, both external and domestic, often at extremely low-interest rates. Increased debt accumulation entails increased economic activity and infrastructure development. If total debt is increasing, questions must be raised as to why this is not reflected in an improvement in Nigerians' standard of living. For instance, between 2004 and 2010, the poverty level increased from 54.7% to 60.9% (Jaiyeola and Bayat 2019) and further increased to 64.61% (Lawanson and Umar 2021) by the end of 2017. As of the end of 2020 and going by the World Bank income threshold of \$3.20 per day, the poverty rate was put at 71% (NNBC 2021).

This article examines how debt stock and service signals affect the annual growth rate of output. When the statements of the debt Laffer curve are re-examined, the link between the debt Laffer curve and non-linearity in the effect of debt becomes obvious. The nonlinear curve links debt stock to repayment abilities (i.e., expected value of repayment). The inverted U-shaped curve depicts how repayment ability declines as the debt stock grows. In other words, after a certain point, efficient debt stock usage drops, and additional debt acquisition leads to a decline in productivity. Nonetheless, the choice of Nigeria for the analysis stems from the fact that apart from being the giant of Africa, her role in regional and continental integration cannot be underestimated. As observed by Eke and Akujuobi (2021), Nigeria's efforts at reducing the poverty level in sub-Saharan Africa speaks volume as contained by Senadza et al. (2018). Above raised fundamental questions about the validity of debt accumulation for economic transformation:

- How far has Nigeria progressed economically in terms of GDP per capita, poverty reduction, life expectancy at birth, literacy rate, and the unemployment rate as more debt is accumulated? and
- Has the level of debt accumulation drastically impacted the economic transformation of Nigeria during the year under review?

This paper uses a holistic measure of sustainable development, considering its multi-dimensional nature, to review Nigeria's debt profile; and examine Nigeria's experiences in terms of debt accumulation viz-a-viz economic transformation in the recent past.

2. LITERATURE REVIEW

Kourtellos, Stengos, and Tan (2012) challenged the idea that the debt-growth link is either consistent across countries or varies significantly with debt levels. They discovered that the hypothesized relationship between public debt and economic development is influenced by institutional quality, but that debt thresholds do not exist. To address the difficulties of unobserved heterogeneity and cross-sectional dependency, Eberhardt and Presbitero (2013) applied novel econometric techniques. Their findings cast doubt on most studies that analyze the empirical relationship between debt and growth using a pooled modeling technique. According to Panizza and Presbitero (2013), OECD countries' average gross debt was close to 110 percent of GDP by the end of 2012, but the net debt was almost 40%. Although net debt is typically lower than gross debt, debt ratios that reflect the government's future implicit liabilities would be significantly higher. Minea and Parent (2012) used the Panel Smooth Threshold Regressions model given by Gonzalez, Terasvirta, and van Dijk (2005), as well as data from Maddison (2007) and the IMF Public Debt Database, to study the relationship between debt and growth (Abbas, Belhocine, El-Ganainy, and Horton, 2011). They discovered that when the debt-to-GDP ratio is greater than 90% but less than 115%, public debt is inversely related to growth. When transitioning from one regime to the next, this approach allows for a progressive shift in the regression coefficient. When debt hits 115 percent of GDP, however, the debt-growth relationship turns positive, according to the researchers. While their findings should not be construed as an endorsement for wasteful spending, they did hint at the existence of complicated non-linearities that exogenous threshold models may not capture.

Similarly, Afonso and Jalles (2013) discovered that throughout the period 1970–2008, the average growth rates of countries with low debt (debt-to-GDP ratio of 30%) were equal to those of countries with high debt (debt-to-GDP ratio > 90%). Reinhart and Rogoff's (2010b) sample is extended back to 1790 by Egert (2012). Using an endogenous threshold model, he discovers a small negative association between debt and growth, as well as some evidence of a non-linear relationship between debt and growth. On the other hand, anticipated endogenous debt-to-GDP thresholds are often far lower than 90%. This entry was published on August 1, 2010. According to the study, minor adjustments in nation coverage, data frequency, and assumptions on the minimum number of observations included in each regime have little effect on the presence and level of the thresholds. A comprehensive analysis of debt growth in Nigeria found that continuing debt accumulation harmed economic growth and so had no bearing on the country's economic transition. According to Adedoyin et al. (2016), there is a significant link between debt and economic growth, but no evidence of Granger causality. The Autoregressive-Distributed Lag's

(ARDL) findings also advised that to minimize the problem of debt overhang, the Nigerian government should set and maintain a maximum debt limit. The same ARDL forms the basis of the investigation by Yusuf and Mohd (2021) where external debt depicted a positive influence on economic growth in the long run but a harmful repercussion in the short run. Hence, governments at all levels were advised to take solace from external borrowing against external financial obligations. Omodero et al. (2020) scrutinized the extent to which external financial obligations in Nigeria affect the general living standard of the people and concluded that borrowed funds did not improve the living standard of Nigerians but rather aided the rising living costs. Not only that, but it was also further observed that the essence of contracting debt has no significant consequence on the living costs of the people because *ab initio*, the purpose was being undermined for lack of political will. In the same way, the outcome of the ARDL bound test by Ohiomo (2020) submitted that both the debt overhang and crowding-out effects variables in his study depressed investment level in Nigeria. Iliya and Tahir (2017) hypothesized external debt and economic growth in a time-series study spanning 1980 to 2014, using the instrument of the Newey-West Heteroskedasticity and Autocorrelation-consistent (HAC) estimator. It was shown that the debt-serving index affects economic growth negatively and significantly. Festus and Saibu (2019) and Ekor et al. (2021) provided further evidence for the debt-growth hypothesis and supported existing findings that the effect of debt on economic growth in Nigeria remained negative. It was further strengthened in the time-series studies that employed ARDL that debt should be channeled solely into productive ventures that will aid the exportation of local outputs.

However, Oyaromade et al. (2021) documented a statistically insignificant relationship between external financial obligation and economic growth in Nigeria. On the impact of debt-bridging resources in Nigeria, Onakoya and Ogunade (2017) postulated institutional checks and balances on government finances if the benefits of external borrowing are to be fully achieved. The outcome of the ARDL estimation method further confirmed that the relationship between debts and economic growth in Nigeria is negative. A similar result was observed by Anderu et al. (2019) where external debt exerted a negative influence on economic growth in Nigeria. The time-series study which employed the same ARDL estimation method for the period 1980 to 2016 suggested a long-term policy that will account for both long- and short-term external debt. There was a mixture of external debt and debt servicing burden in the study by Ndubuisi (2017) where the error correction test showed that the debt servicing effect on economic growth in Nigeria was insignificant whereas, debt has a pronounced implication on economic growth. On the contrary, both external debt and debt servicing were shown as having negative and significant consequences on economic growth in Nigeria in another study by George-Anokwuru and Inimino (2020). Amassoma (2011) posits that internal debt, not external debt, will aid Nigeria's economic growth. This is because repaying the internal debt principal and interest is a reinvestment in the local economy, which would normally have an impact on chain investment. Foreign debt, on the other hand, will necessitate additional resources to repay and service the loan, diminishing the debt's favorable influence on economic growth. As a result, rather than relying on external debt to stimulate the economy, the government should rely on internal debt.

After showing the presence of a negative relationship between debt and growth, Cecchetti, et al. (2012) explored non-linearities. In standard regressions and group comparisons, they identified no indication of a threshold effect. Nonetheless, they stated that evidence from more advanced econometric approaches indicated the presence of such an effect. From 1970 to 2007, Kumar and

Woo (2010) explore the relationship between debt and growth in a sample of 30 advanced and developing market nations. They tested various estimate methods and discovered that the system GMME helps them deal with endogeneity. A 10% increase in the initial debt-to-GDP ratio is related to a 20% slow in yearly real per capita GDP growth (Cecchetti et al. 2012). This data should be treated with caution. Difference and system GMM estimators were designed for microdata and are therefore ineffective for macroeconomic datasets with a small number of cross-sectional units (Bond, 2002). From 1970 to 2008, Checherita-Westphal and Rother (2012) compare a country's debt-to-GDP ratio to the average debt-to-GDP ratio of the other 11 euro-area nations at the same time. Using this method, the authors establish a non-linear hump-shaped relationship between debt and growth. Growth peaks when the debt-to-GDP ratio is between 90 and 100 percent, according to their calculations. Checherita-Westphal and Rother's instrument have two flaws (2012). The tool is only viable if "there is no strong association between debt levels in other euro area countries and the per-capita GDP growth rate in a single country" (Checherita-Westphal and Rother, 2012). This assumption is tough to refute. If debt hurts a country's growth, claiming that debt levels in other euro-area countries have no impact on growth in the excluded country is equivalent to claiming that GDP growth in the euro area (as calculated by excluding a specific country from the group) has no impact on GDP growth in the excluded country. It is significantly more difficult to justify such an argument during a crisis when there is convincing evidence of massive cross-country spillover effects (De Santis, 2012). Second, like the GMM estimations discussed above, Checherita-Westphal and Rother (2012) use instrumental variables to get results that are quite close to those of OLS regressions. This could indicate that the debt is not endogenous or that the instrument is malfunctioning. Panizza and Presbitero (2012) employ the same specification as Cecchetti, Mohanty, and Zampolli (2012), but factor in the value implications of foreign currency debt and exchange rate fluctuations. The paper shows that the instrument is useful (as indicated by a satisfactory first-stage correlation and a battery of weak instrument tests), but it is unable to assess the validity of the exclusion constraint since the model is not explicitly described.

However, most studies focus on the relationship between public debt and economic growth, while studies using Johansens' cointegration technique applied to public borrowing, economic, and sustainable development in Nigeria are still scanty. The purpose of this article is to apply the technique to inform policymakers about whether or not public borrowing helps economic and sustainable growth in Nigeria. This will help the government allocate resources from the public debt to other important sectors of the economy.

2.1 Theoretical Framework

There are numerous economic growth theories. The theories are essentially diverse in that they make various behavioral assumptions, employ different ideas and categories, explain the development process differently, and propose different strategies (Mookherjee & Ray, 2001). The Economic Base Theory is one of the economic development theories that consider economic development to be the pace of local economic growth as measured by changes in output, income, or employment. The core sector's response to international demand for local exports, which fosters local growth, is the idea's primary dynamic. Acceptance as a foundation for understanding economic progress in North America, as well as its simplicity as a hypothesis or instrument for prediction, are two of the idea's main attributes (Malizia and Feser, 1999). Its main flaw is that it is insufficient as a theory for comprehending economic development, particularly over long

periods. According to economic theory, enticing the sector through recruitment and location marketing is a good strategy.

The staple idea is another economic growth hypothesis. This concept's main assumption is industrial sectors. Long-term sustainable growth is described as economic progress (Ray, 1998). Two of the theory's main strengths are its historical connection to North American economic development and its emphasis on understanding the region's economic history. Its fundamental problem is that it describes rather than explains the development process (Hoff and Stiglitz, 1999). As part of the economic growth process, this idea was developed. The globe is divided into three categories: primary, secondary, and tertiary (Aghion & Bolton, 1997). Sectoral diversity, with a focus on the tertiary sector, as well as labor productivity, determines the level of development. The basic, secondary, and tertiary categories are too crude to be effective in practice, even though Sector Theory may be applied and tested empirically (Todaro & Smith, 2009). The most essential application is that for long-term growth, sectors that create income-elastic goods must be prioritized. In the classical liberal approach, economic development is characterized as economic growth and capital formation. Capital production, according to this idea, is the cornerstone of the economic growth of large-scale infrastructure projects and international aid funds were emphasized as a result (Fields, 1981). In social theories of economic development, the importance of human capital has been emphasized. Economic growth is influenced by factors such as education, health, and fertility. They moved their focus from total economic growth to poverty, inequality, urbanization, and other social problems (Ferreira et al. 2010).

The conditions unique to Third World countries are highlighted in economic structural theories. Recognizing that the European model could be duplicated in former colonies was crucial to economic success (Ray, 1998). Under the idea, concerns were shifted to "import substitution," high tariffs, and government protectionism. Neo-classical economic development theories emphasize the negative consequences of development. Economic prosperity depends on free markets. They shifted the focus of structural theories away from the government and toward private investment and market efficiency. Currently, this is the most widely utilized set of hypotheses (Mookherjee & Ray, 2001; Malizia & Feser, 1999). Other economic development theories include the growth pole theory, interregional theory, product-cycle theory, entrepreneurship theory, and flexible production theory. The Classical Liberal and Social theories are chosen in this study because they identify and incorporate human capital into the definition and assessment of economic progress. Using Human Development Index (HDI) factors, the study compared Nigeria's economic advancement to the country's overall public debt. The HDI has been widely used by UN agencies and other international organizations to analyze both economic and human progress since 1990. HDI is gaining popularity among development economists (Nagel, 2007).

Sachs (1989) developed a theoretical model known as the "debt overhang for developing countries," which proved that debt forgiveness might raise the value of future debtor country repayments while preserving the current market value of debt instruments. This is especially true when a country borrows excessively and is forced to face the debt-servicing load. When a country's debt becomes too large, it loses its ability to finance it, increasing the danger of default. Creditors consider those factors when calculating the expected value of repayments they can expect from a sovereign, and if that value is less than the face value of the debt, it may be the case that lowering

the face value of the debt reduces the likelihood of a country defaulting on interest or principal payments, and thus increases the expected value of repayments to creditors, as explained later. The possibility of market-based debt reduction measures is explained by Krugman (1989), who also provides Sachs' idea on a formal basis. When a country's debt exceeds its ability to pay, or "when a country's responsibilities exceed the amount it is likely to be able to pay," these obligations act as a high marginal tax rate on the country: if it does better than expected, the main benefits will accrue to its creditors, not the country. Because all of the advantages will go to the creditors rather than the country, the domestic government will be discouraged from doing well and improving its economic performance. The debt, on the other hand, must be repaid by domestic taxpayers, mostly through capital taxes, which would dissuade investment even more. Krugman then goes on to explain the debt Laffer curve's underlying logic, as seen in Figure 1, pointing out that the relationship between the debt's face value and its market value is one-to-one up to a point. When the face value of a security exceeds this level, the market value begins to rise more slowly. The reason for this mismatch is that as the debt develops, financing becomes more difficult due to larger service commitments, which effectively act as a tax on investment, policy reforms, and other activities that require upfront costs in exchange for future benefits (Epaphra and Mesiet 2021). The total market value of debt declines as more debt is accumulated, and the marginal return on debt to the right of point A begins to decline, while the total market value of debt rises. When debt levels exceed a particular threshold, the absolute growth in face value is insufficient to offset the marginal decline in market value, the country is said to have a "debt overhang":

Figure 1: Debt Relief Laffer Curve

When a country's debt level at face value is related to a lower market value, there are two options: the country is either on the left or right side of point B. Point B represents the maximum market value of a country's debt. If a country's debt level correlates to a location on the debt Laffer curve between A and B, it is considered to be on the "right" side of the debt Laffer curve. In this case, debt forgiveness will not result in a higher market value for the debt. If, on the other hand, a country's debt level corresponds to a point on the curve to the right of point B, the country is said to be on the "wrong" side of the Laffer curve, i.e., it has a debt overhang. In this situation, debt

forgiveness will lower the face value of a country's debt while increasing the market value of that debt.

3. METHODOLOGY

There is ambiguity in the measure of sustainable and inclusive development (Rauniyar & Kanbur, 2009). Several studies have used different measures such as poverty, educational indicators, and HDI to proxy sustainable development. In recent times, studies are beginning to use the growth-elasticity of poverty as a measure of economic development and sustainability (Klasen & Misselhom, 2008; Habilo, 2009). In our analysis, we take cognizance of the fact that economic development and sustainable development are about the expansion of human capabilities for economic productivity.

Our methodology encompasses both theoretical and econometric analysis. The theoretical analysis is used to assess Nigeria's debt profile, which is the first objective of the study. Using empirical evidence, the study investigated looked into the relationship between Nigerian debt and economic development, and how the former influenced the latter. The study covers the period between the years 2000 and 2020. The choice of this period coincides with the beginning of the present democratic rule in the country cum the significance attached to economic growth and development by various governments. The economic and sustainable development is broken down into proxies namely: GDP per capita (GDPpc), Literacy Rate (LITRT), Population Rate below Poverty Level (PPL), and Total Debt (TDT). They were selected in line with the principles of the UNDP approach to inclusive development. The *a priori* expectation is that as total debt stock increases, GDPpc, and LITRT would have positive signs while PPL is expected to reduce. The analysis was done using the E-Views Software. There are various approaches to estimating cointegration regressions. However, this paper adopts Johansen's cointegration method because, like others, it allows for more than one cointegrating relationship. Moreover, recent Monte Carlo evidence strongly favors Johansen Maximum Likelihood Method (JML) over the Engle-Granger method (De Jong, 1992 cited in Ogujiuba et al, 2004). The hypothesis is that if the variables are cointegrated, they share a long-run relationship and will move closer together over time.

Cointegration analysis is used to obtain information about the long-term equilibrium relationship of the model. Initially, economists used linear regression on non-stationary time series data, but following Granger and Newbold (1974), it is now widely accepted that most economic time series are non-stationary in their levels; and using such data sets may produce spurious regressions. This assumes that the means and variances are time-dependent and that such variables are first-order integrated. As a result, all statistics in a model based on these series vary over time, and these variables fail to converge to their true values as the sample size grows (Rao, 1994). To avoid spurious regression, the Augmented Dickey-Fuller would be employed to test for the presence of unit roots. The presence of a unit root is the null hypothesis, while the absence of a unit root is the alternative hypothesis. Granger (1981) and Engle and Granger (1987) argue that the presence of cointegration must be taken into account when testing the relationship between two variables that have unit roots. To do this, the standard procedure is to conduct an ordinary least square regression after differencing the data. The presence of a unit root justifies the estimation of the equations within a cointegration framework. However, cointegration analysis is more appropriate when the data sets are of limited strength which is peculiar to time series analysis as in this case.

In line with a study by Olamide and Maredza (2021), the equation of the study is expressed as:

Total Debt and GDP per Capita: Long-run relationships

$$GDP_{pc_t} = \alpha + \beta TDT_t + \mu_t \dots\dots\dots (1)$$

Total Debt and Literacy Rate: Long-run relationships

$$LITRT_t = \alpha + \beta TDT_t + \mu_t \dots\dots\dots (2)$$

Total Debt and Population below Poverty Line: Long-run relationships

$$PPL_t = \alpha - \beta TDT_t + \mu_t \dots\dots\dots (3)$$

Where:

- TDT Total Debt
- GDP_{pc} GDP per Capita
- LITRT Literacy Rate
- PPL Population below Poverty Line
- α The Intercept
- β - Beta Coefficient of the Independent Variable
- μ Standard Error of the Estimate

3.1 Sources of Data

As stated above, data on economic progress was split down into proxies and sourced from the Statistical Bulletin of the Central Bank of Nigeria (CBN), the National Bureau of Statistics (NBS), the International Monetary Fund (IMF), and the World Bank Economic Statistics, respectively.

4. RESULTS AND DISCUSSION

Objective 1: Stylized Facts of Nigeria’s Debt Profile

In a study published in 2013, World Economic Outlook determined a provisional threshold of 50% for total public debt to GDP for emerging markets. Table 1 shows that Nigeria's ratios were above that threshold before the Paris Club debt settlement in 2005. The entire public debt/GDP ratio declined to 12.39 percent at the end of 2006 after quitting both the Paris and London Club debt obligations, while the total public debt stock fell to 2,239.11 billion Naira (US\$ 17, 349.69 million). In 2007, this ratio fell to 11.67 percent, 8.53 percent in 2008, 6.49 percent in 2009, 6.38 percent in 2010, and 5.74 percent in 2011. However, the ratio started rising again from 22.9% in 2014 to 23.41% in 2016 and 35% in 2020. This marked the beginning of the rising debt profile of the country after the initial cancellation by the Obasanjo administration.

Table 1: Trends in Nigeria’s debt profile 2000-2020

| Year | GDP GDP (Naira Bn) | Total Public Debt (Naira Bn) | TDP/GDP (Naira Bn) |
|------|-----------------------|---------------------------------|-----------------------|
| 2000 | 6.9 | 4,210.96 | 61.07 |
| 2002 | 7.8 | 5,155.72 | 66.13 |
| 2004 | 11.4 | 6,147.88 | 53.88 |
| 2006 | 18.1 | 2,239.11 | 12.39 |
| 2008 | 24.3 | 2,848.84 | 8.53 |
| 2010 | 34.0 | 5,323.46 | 6.38 |
| 2012 | 45.5 | 8,013.22 | 20.24% |
| 2014 | 54.7 | 9,465.98 | 22.9% |
| 2016 | 44.7 | 10,876.45 | 23.41% |

| Year | GDP (Naira Bn) | Total Public Debt (Naira Bn) | TDP/GDP (Naira Bn) |
|------|----------------|------------------------------|--------------------|
| 2018 | 57.2 | 16,352.31 | 27.69% |
| 2020 | 72.3 | 22,769.69 | 35% |

Source: CBN, DMO

Nigeria's external debt stock was US\$5.6 billion as of December 31, 2012, down from US\$6.3 billion the previous year. The debt stock increased from US\$ 3.0 billion (representing 83.6 percent) in 2001 to roughly US\$ 18 billion in 2005 (representing 83.6 percent). Although the Non-Paris Club's debt stock declined steadily from 2001 to 2004, it skyrocketed in 2005 due to increased disbursements of Chinese loans. However, the implementation of Phases I and II of the Paris Club debt arrangement resulted in a drop to US\$2.4 billion in 2006. Between 2007 and 2008, the external debt stock dropped even further, to US\$2.1 billion and US\$2.0 billion, respectively. However, between 2014 and 2020, the debt stock has risen astronomically beyond the acceptable threshold.

| | 2000 | 2002 | 2004 | 2006 | 2008 | 2010 | 2012 | 2014 | 2016 | 2018 | 2020 |
|------------------------|-------|-------|-------|------|------|------|------|------|------|-------|-------|
| External Debt (USD\$b) | 28.27 | 23.51 | 28.22 | 2.13 | 2.06 | 2.58 | 3.82 | 6.45 | 7.84 | 21.04 | 28.57 |

Note Exchange rate – Naira (N) per US\$: 2000 – N100.6, 2002 – N126.9, 2004 – N132.3, 2006 -N127, 2008 - N131.3, 2010 – N149.2, 2012 – N157.5, 2014-N158.6, 2016-N253.5, 2018-N307, 2020-N381.

Since 2000, the accumulation of arrears, the country's debt portfolio's foreign exchange exposure, and the depreciation of Nigeria's external debt reporting currency have all contributed to the rise of Nigeria's external debt stock (Table 2). From 2003 to -2004, Nigeria's foreign debt to EU countries was consolidated into Euro, and the Euro's subsequent appreciation against the US Dollar was a major factor in the country's debt stock increasing. Between 2000 and 2004, the external debt stock increased by US\$1.6 billion. (According to DMO, 2009).

Table 2: Total Domestic Debt Stock

| | 2000 | 2002 | 2004 | 2006 | 2008 | 2010 | 2012 | 2014 | 2016 | 2018 | 2020 |
|---------------------|---------|--------|--------|--------|--------|--------|--------|-------|---------|---------|---------|
| Domestic Debt (NTn) | 0.898tr | 1.67tr | 1,37tr | 1,75tr | 2,32tr | 4.55tr | 6.54tr | 7.9tr | 11.06tr | 12.77tr | 16.02tr |

Source: DMO, Budget Office, CBN 2021.

The composition of Nigeria's domestic debt by instruments includes Federal Government of Nigeria bonds, Treasury Bills, Treasury bonds, development stocks, and Promissory Notes.

The domestic debt stock in Nigeria increased from N0.898tr to N6.5tr over the period 2000–2012. Between 2010 and 2012 alone, it increased by 22.08%, representing an increase of N1.99tr. Since 2000, the accumulation of arrears, the country's debt portfolio's foreign exchange exposure, and the depreciation of Nigeria's external debt reporting currency have all led to an increase in Nigeria's external debt stock (Table 2). Nigeria's foreign debt to EU countries was consolidated into Euro in 2003-2004, and the Euro's subsequent appreciation against the US Dollar was a major contributor to the country's rising debt stock. Between 2000 and 2004, the stock of external debt increased by US\$1.6 billion. (For more information, see DMO, 2009). Between 2014 and 2018, Nigeria's debt increased from 7.9tr to 12.77tr and 16.02tr by the end of Dec 2020. Responsible for this largely was the fall in global commodity prices compounded by the Covid-19 global pandemic.

Table 3: Components of Domestic Public Debt by Instruments

| | 2007 (N 'B) | 2008 (N 'B) | 2009 (N 'B) | 2010 (N 'B) | 2011 (N 'B) | 2015 (N 'B) | 2019 (N 'B) |
|--------------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| Treasury bills | 574.9 | 471.9 | 797.5 | 1,277.1 | 1,727.9 | 2,346.5 | 2,875.4 |

Source: CBN

Table 4 and Figure 1 show the composition of domestic debt by instrument between the end of 2007 and 2011. Treasury bills stood at N574.9 billion in 2007. It declined to N471.9 billion in 2008. It increased sharply to N797.5 billion in 2009, N1, 277.1 billion in 2010, and N1, and 727.9 billion in 2011, respectively.

Figure 2: Components of Domestic Public Debt by Instru

Treasury bonds declined from N407.9 billion in 2007 to N353.7 billion in 2011. Development stock recorded 0.6, 0.5, 0.5 and 0.2 per cents in 2007, 2008, 2009 and 2010. FGN bonds amounted to N178.4 billion in 2007 and promissory notes N63 billion in 2009. Between 2015 and 2019, the values of the components of public debt instruments have risen astronomically.

Table 4: Debt Solvency Indicators

| Item | Actual | | | | Thresholds |
|--------------------------|--------|------|------|------|------------|
| | 2009 | 2011 | 2015 | 2018 | |
| Total debt to GDP | 15.40 | 18 | 20 | 25 | 40 |
| External Debt to Exports | 8.50 | 14 | 28 | 42 | 100 |
| Total Debt to Revenue | 144.30 | 195 | 200 | 220 | 250 |
| Debt service to Revenue | 20.60 | 22 | 23 | 26 | 30 |
| Debt service to Exports | NA | NA | NA | NA | 20 |

Sources: CBN Annual Report and Statement of Account 2010; 2015; 2018 Debt Sustainability Analysis Report and National Institute for Legislative Studies Reports

Current debt and debt-service ratios show worrisome results, vis-a-vis the current thresholds of the federal government Debt Sustainability Analysis (DSAs). The DSAs report by the DMO in 2010 and the Debt Management Framework for 2009-2018 prescribed the following ratios: Total debt to GDP 40%; External debt to Exports 100%; Total Debt to Revenue 250%; Debt service to Revenue 30%; and Debt service to Exports 20% (see Table 5).

Between 2009 and 2020, the total debt-to-revenue and deficit-to-revenue ratios are expected to rise. Given that the federal government has no plans to outsource external debt other than domestic debt, traditional indicators of a country's ability to repay debt, such as GDP, exports, and fiscal revenue, are expected to rise. The negative consequences of the global financial crisis between 2007 and 2009, the economic breakdown from 2014 to 2017, and the COVID-19 pandemic on most low-income countries' economic activity could have been imagined rather than real. In Nigeria, these scenarios have resulted in humongous debt accumulation without much impact on the socio-economic status of the country just as the security challenges facing the country have continued unabated. This suggests that the debt threshold of the country must have gone beyond the manageable level. Therefore, more stringent ratios are required to reduce debt susceptibility and fortified fiscal revenue. Nigeria's disposition to borrow pointed to the fact that external debt has been harmful to growth either because these loans were channeled to unproductive elephant ventures, or they find their way out of the country through corrupt practices (Eke & Akujuobi 2021; Rotimi et al., 2021). Olamide and Maredza (2021) in South Africa confirmed the negative impact of external debt on the country's economic growth. Using the ARDL estimating approach, it was also discovered that corruption had a regressive and harmful impact on the country's development goals. The debt-growth debate in Africa has revealed a negative link (Senadza et al. 2018, Mwakalila 2019). However, Epaphra and Mesiet (2021) concluded that a moderate level of debt-growth ratio helps boost the economic growth of the region just as Bett (2018) opined that foreign borrowing exposes the borrower to external interference by the lender. On the contrary, Elwasila (2018) concluded that external debt had a beneficial effect on economic growth in Sudan from 1969 to 2015. Shkolnyk and Koilo (2018) found that rising debt levels paired with macroeconomic instability stymies economic change in Ukraine, citing the government's debt management problem as the source of the country's macroeconomic instability. Debt also aggravates growth in Bangladesh according to a study by Dey and Tareque (2019).

Objective II:

Our second objective investigates the long-run relationship between debt accumulation and economic and sustainable development. Then Akaike information criterion (AIC) is used to specify the lag as depicted in table 5. Accordingly, the results suggest that VAR at lag 1 1 is more suitable.

Table 5: Lag Order Selection

| Lag | Logl | LR | FPE | AIC | SC | HQ |
|-----|-----------|-----------|-----------|-----------|-----------|-----------|
| 0 | -1439.271 | NA | 5.39e+33 | 94.0184 | 94.11530 | 94.0782 |
| 1 | -1321.867 | 183.0264* | 7.09e+29* | 95.31365* | 88.14796* | 86.52254* |
| 2 | -1312.714 | 6.201430 | 0.69e+34 | 96.03846 | 88.63852 | 87.49931 |

Source: Authors' computation using E-View

The next step is to apply the Johansen maximum likelihood approach to determine whether the variables have a long-term relationship. Table 6 shows the test findings, which compare the null hypothesis of no co-integration with the alternative hypothesis of the presence of co-integration, using maximal-eigenvalue statistics. In this method, the co-integrating vector is considered to stay constant during the study period. The government's current reform attempt may impact the long-run linkages between the underlying factors. This is particularly true if the sampling interval is long.

Table 6: Johansen Maximum Likelihood Co-Integration Tests

| | Eigen Value | Likelihood Ratio | 5% Critical Value | 1% Critical Value | Hypothesized |
|--------------------|-------------|------------------|-------------------|-------------------|--------------|
| For GDP TDT | 0.914508 | 34.04149 | 15.41 | 20.04 | None ** |
| | 0.314402 | 4.529564 | 3.76 | 6.65 | At most 1 * |
| For LITRT | 0.558696 | 11.32670 | 15.41 | 6.65 | None |
| TDT | 0.118271 | 1.510449 | 3.76 | | At most 1 |
| For PPL TDT | 0.828655 | 16.36043 | 15.41 | 20.04 | None ** |
| | 0.233541 | 1.191693 | 3.76 | 6.65 | At most 1 |

*(**) denotes rejection of the hypothesis at a 1% (5%) significance level

L.R. test indicates 2 cointegrating equation(s) at 5% significance level

The statistical result in Table 6 indicates that a positive relationship exists between GDP and the total debt profile of the federal government. The hypothesis is positively significant at 5% and 1% critical values. However, it reveals two co-integrating equations at a 5% significant level. It has however been argued that Nigeria's economy is debt-dependent and therefore susceptible to domestic shocks (Yusuf and Mohd 2021).

There was no indication of a long-term relationship between literacy and total state debt in Nigeria in table 6. At a 5% significance level, the long run rejects any co-integration. At both the 5% and 1% significant levels, the null hypothesis of the likelihood ratio is accepted. According to the data, there was no impact of public debt on literacy rates throughout the period studied. At both the 5% and 1% significance levels, the max-eigenvalue statistics in the Table above indicate rejection of the hypothesis, as well as acceptance that the long-run test reveals one co-integrating equation at the 5% significance level. According to the findings, there is no link between poverty and overall governmental debt. Available statistics indicate that the Population below the Poverty Line rate increased from 34.1% in 1999 to 60% in 2000. The rate remained at 60% between 2000 and 2009. It increased to 70% from 2010-to 2012. During the same period, the real GDP growth rate did not follow a particular pattern. For instance, it stood at 2.7% in 1999, 3.5% in 2000, 3.5% in 2001, 3.0% in 2002, 7.1% in 2003, 6.2% in 2004, 6.9% in 2005, 5.3% in 2006, 6.4% in 2007, 5.3% in 2008, 5.6% in 2009, 8.4% in 2010, 10.2% in 2015, 15% in 2018 and more than 20% in 2020

Diagnostic Tests

Three post-estimation tests were performed to ensure the fitness and reliability of our model. Table 7 below gives details.

Table 7: Model Fitness and Reliability Results

| Serial Correlation [Null hypothesis: no serial correlation] | | | | | | |
|---|----------|------------------|----------|-------------|------------|--------|
| Lag | LRE*Stat | df | Prob. | Rao- F-Test | Df | Prob. |
| 1 | 2.835774 | 4 | 0.4016 | 0.980142 | (4, 213.0) | 0.4016 |
| 2 | 3.763765 | 4 | 0.3401 | 1.215398 | (4, 213.0) | 0.3401 |
| Jarque-Bera Normality test | | | | | | |
| | | Jarque-Bera Stat | Prob. | | | |
| | | 2.386418 | 0.321029 | | | |
| Breusch-Pagan-Godfrey Heteroskedasticity Test | | | | | | |
| F-Statistics | 0.005461 | Prob. F (1, 109) | 0.9501 | | | |
| Obs*R-Square | 0.005573 | Prob. Chi-Square | 0.9491 | | | |
| Explained SS | 0.003298 | Prob. Chi-Square | 0.5108 | | | |

Source: Authors' compilation using EViews

The VAR residual serial correlation LM test was used to generate Table 7. Because the p-values exceed the 5% benchmark, we cannot reject but must accept the null hypothesis of no serial association. The Jarque-Bera test yielded a statistic value of 2.386418 and a corresponding p-value of 0.321029, which is higher than the 5% threshold. As a result, the model's residuals can be assumed to be regularly distributed. As a result, the null hypothesis of the non-normal distribution of the residuals is rejected, whereas the alternative hypothesis of the normal distribution is accepted. It can be concluded from Table 7 above that the model is not heteroskedasticity but homoskedasticity since the p-values are more than the 5% benchmark. Therefore, the model's residuals have constant variance and are good for the study.

Table 8: Variance decomposition

| Period | Variance Decomposition for LGDPpc | | |
|----------------------------------|-----------------------------------|-----------|-----------|
| | Std Error | LGDPpc | TDT |
| 1 | 0.012053 | 100.00000 | 0.000000 |
| 2 | 0.017428 | 89.84034 | 0.017738 |
| 3 | 0.021204 | 89.82416 | 0.048749 |
| 4 | 0.024123 | 89.80603 | 0.152441 |
| Variance Decomposition of TDT | | | |
| 1 | 1.206034 | 18.114392 | 83.647244 |
| 2 | 1.714048 | 17.482941 | 84.104201 |
| 3 | 2.201047 | 17.346719 | 84.048244 |
| 4 | 2.740614 | 16.949196 | 83.899496 |
| Ordering of Cholesky: LGDPpc TDT | | | |

Source: Authors' compilation using EViews

From table 8 above, it is indicative that apart from shock to itself, the effects of shock from gross domestic product per capital on TDT became noticeable by the fourth period with a value of 15.24%. Any shock from GDPpc has no effect during the first period but recorded a small effect of 4% by the third period. However, the effects of shocks from TDT on the gross domestic product were more felt in the first and second quarters of the period under investigation. These effects reduced marginally to 17.35% and 16.95% during the third and fourth periods respectively. Economically, this seems reasonable since total debt is not the only variable that can shock GDPpc.

5. CONCLUSION

Debt has a short-term favorable impact on growth, but it has a long-term negative impact. Massive public debt may not have an immediate influence on economic growth, but if used properly, it has the potential to be a huge positive in the long run. Nigeria's entire public debt, according to the data, has hurt its economic and sustainable development efforts during the study period. Classic liberal and social theories were embraced because they identified and integrated human capital into the concept and evaluation of economic success. Human Development Index (HDI) proxies such as literacy rate, population below the poverty line, and GDP per capita were utilized in the study. With governmental debt borrowing (both external and domestic debt), the study variables were expected to improve, however, the opposite proved true. According to the findings, there is a link between GDP per capita and the federal government's total debt profile. During the study period, the literacy rate, total debt, population below the poverty line, and total debt were all statistically insignificant. Nigeria is accruing a new level of financial burden, according to statistics. If the debt level climbs above a particular threshold, the absolute gain in face value will not be enough to compensate for the marginal decline in market value, and the government would face a future "debt overhang." This study supports the Debt Relief Laffer Curve if Nigeria

continues to build her debt profile without physical development to justify the borrowings. Generally, in managing public debt, attempts must be made at ensuring fiscal sustainability with adequate concern to ensure that the debt profile does not exceed the discounted value of its expected net revenue.

5.1 Recommendations

Based on the study's findings and conclusions, it is suggested that:

- i. The Nigerian government should investigate the reasons for the non-contribution of public debts to human development indices to identify and eliminate bottlenecks. This could be due to poor administration, corruption, greater financing costs, or a failure to target the relevant population segment.
- ii. Debts are intended to boost the debtor country's economic growth and development, as well as the citizens' standard of living. As a result, the Nigerian government should always regard indebtedness as a means to long-term economic and sustainable development, rather than only as a method to solve short-term problems.
- iii. Reforms targeted at strengthening policy and institutional performance, notably in the areas of economics and debt management, should be bolstered.
- iv. It is necessary to examine stronger fiscal positions and better financing terms from donors/creditors.

ENHANCING TEACHING AND LEARNING THROUGH EDUCATIONAL TECHNOLOGIES IN SOUTH AFRICA'S HISTORICALLY DISADVANTAGED INSTITUTIONS

H. Shava

Walter Sisulu University, Butterworth, South Africa

ABSTRACT

After the outbreak of the COVID-19 pandemic, the majority of historically disadvantaged institutions (HDIs) in South Africa approved and adopted educational technologies to continue teaching and learning activities. Although this was a move in the right direction, very little is known in research as to whether HDI educators are effective in the use of educational technologies. Quantitative data was collected from students who were asked to evaluate the effectiveness of educators on four dimensions of online teaching and learning, namely virtual interaction, unit content migration, online course alignment, and web-based module structure. This study is descriptive by design. Descriptive statistics were used to make meaning of the data. The results reveal that HDI educators are effective with regard to four dimensions of online teaching and learning, namely virtual interaction, unit content migration, online course alignment and web-based module structure. Although literature points out that prior to the COVID-19 outbreak, HDI educators had little experience in the use of online educational technologies, the study's findings reveal that HDI educators are capable of making use of educational technologies for the purposes of online teaching and learning. To ensure that online teaching and learning is enhanced within HDIs, this study recommends that stakeholders in the higher education sector should work together to reduce the digital divide gap as it hinders students from harnessing the full potential of e-learning.

Keywords: Historically disadvantaged institutions; educational technologies; teaching and learning; university graduates; employment.

1. INTRODUCTION

South Africa's historically disadvantaged institutions (HDIs) still battle to establish themselves as universities of choice when compared to their affluent counterparts. The resources divided among South African institutions of higher learning play a critical role when it comes to graduate absorption in the labour market. It is widely perceived that graduates from affluent universities find work relatively easier than graduates from HDIs. This study argues that HDIs have the opportunity to perform at the same level and enhance their graduates' employability perception by effectively utilising online educational technologies that are widely and primarily used by South Africa's affluent universities.

In the year 2019, the Internet of Things (IoT), Machine Learning and Big Data were the major educational, technological movements. One year down the line, COVID-19 came about and changed how teaching and learning are practised (Mbhiza, 2021). Since the world came to a better understanding of the COVID-19 virus after its widespread outbreak, distance learning became the major trend as authorities across the globe implemented lockdowns to prevent further spread of

the deadly virus (Maringe, 2020). Distance learning became the major movement owing to social distancing implications. Most South African institutions have teaching and learning facilities that accommodate a limited number of learners. With the implementation of social distancing regulations, conducting lectures in the classroom became impossible. In other words, most public agencies could not execute their mandate in South Africa (Haffejee & Levine, 2020), and globally (Fallon, McGhee, Davies, MacLeod, Clarke & Sinclair, 2020).

To ensure that teaching and learning continued smoothly, blended learning was adopted by all South African universities including the HDIs. Blended learning incorporates the traditional and online teaching and learning approaches. On the one hand, traditional teaching refers to teaching activities in a given facility where both the educator and the learner are physically present. On the other hand, online teaching and learning refer to a scenario whereby teaching and learning take place virtually as aided by educational technologies.

HDIs in South Africa are primarily found in rural areas and or in small towns where the infrastructure needed to support good Internet connectivity is very poor, the so-called digital divide (Dube, 2020). Research by Van Deursen and Van Dijk (2019) explained the digital divide gap as the gap between those who have access to computers and the Internet and those who do not. With reference to the digital divide gap in South Africa's higher education sector, they pointed out that this gap is huge, and it negatively affects the feasibility of online teaching and learning. Mpungose (2020) observed that the digital divide in South Africa's higher education sector is hindering students from realising the full potential of online teaching and learning. Du Plessis and Mestry (2019) described rural areas as secluded and poorly developed. The other challenge is that HDIs have a smaller financial muscle than the affluent and formerly whites only universities, the so-called resources divide (Mabokela & King, 2001). Poor Internet connectivity supporting infrastructure and insufficient financial resources are perennial problems, which have affected HDIs and contribute immensely to poor graduate employability as most of their graduates lack exposure and work-integrated learning experience (Nyahodza & Higgs, 2017; Tapfumaneyi & Rupande, 2013).

Most of the HDIs have curriculums developed to allow them to continue functioning despite the poor financial resources, for example, by having little practical and no work-integrated learning component for most of the qualifications on offer (Singh, 2004). Resultantly, HDIs were the main users of the traditional teaching and learning approach where learners would gather in a lecture room with a lecturer facilitating the learning activities for the day. This approach highly accommodated their financial and technological infrastructure circumstances (Lipowsky & Rzejak, 2015). HDIs' over-reliance on the traditional approach resulted in them temporarily shutting down learning activities after the outbreak of the pandemic owing to inadequate technological infrastructure to support fully the demands of the online teaching and learning (Mhlanga & Moloi, 2020). On the resources divide debate, Maringe (2020) concluded that HDIs do not have sufficient infrastructure to support the demands of online and teaching activities.

Although legislation has been passed and funding from the government increased with a view to bridging the historical gaps between affluent universities and HDIs (Bunting, 2006; Mzangwa, 2019), history continues to detect how institutions of higher learning position themselves concerning the adoption and utilisation of educational technologies (Ng'ambi et al. 2016). Given the advent of educational technologies, HDIs do stand a chance to enhance their educational

experience and enhance the attractiveness of their graduates in the labour market. Empirical evidence supports this notion, as research by Shava (2022) found that online teaching and learning predicts graduate employability in South Africa's rural universities.

Research further argues that if educators are highly effective and innovative in their adoption and implementation of educational technologies, various skills of learners befitting the 21st working environment could be enhanced leading to their improved graduate employability perception (Edmunds, Thorpe, & Conole, 2012).

Conversely, evidence suggests that educational technologies per se are not an issue, instead, the challenges lie in educators' abilities to embrace the available technology for online teaching and learning (Watty, McKay & Ngo, 2016). In the same vein, Mayberry et al. (2012) observed that the correct application of educational technologies for the purposes of online teaching and learning is a daunting task for many educators in universities. Van Duersen and van Dijk (2019) refer to the described phenomena as the second digital divide, where the right attitude and skills for the correct use and application of online educational technologies is more like a permanent problem in the South African context. Maringe (2020) noted that for effective online teaching and learning to take place, universities should consider retraining educators and possibly recruit additional educators whose competencies in the context of the new delivery mode is beyond questionable. Mbhiza (2021) concurred with the above notion and pointed out that after the Covid-19 outbreak, South African educators and learners had to rely on online teaching and learning, yet most had little knowledge, skills and training on how to utilise such technologies. In the case of HDIs, the majority of both educators and learners had to adopt a hands-on approach, that is, learn by doing to get the work done (Dube, 2020). Research concurs and points out that owing to resource scarcity in HDIs and poverty among African and Coloured students, access to educational technologies remains a challenge in South Africa (Dube, 2020; Mhlanga & Moloji, 2020).

Given the mentioned background, research focusing on educator effectiveness in the use of online educational technologies from the context of HDIs in South Africa is of paramount importance. Conversely, research showing that learners have been utilising educational technologies for knowledge sharing and learning in South Africa's rural universities does exist (Shava & Chinyamurindi, 2018; Shava, Chinyamurindi & Somdyala, 2016). However, not much research has been undertaken to investigate educators' effectiveness in utilising online technologies. This study fills this void and the conclusions are drawn from students' perception of the performance of educators across four dimensions of online teaching and learning.

Research on this subject is critical given that technological innovation within South Africa's higher education sector has a transformational effect on teaching and learning and therefore, educator effectiveness in the use of educational technologies cannot be overlooked (Mayberry et al. 2012; Zarei, Kheiri, & Yazdgerdi, 2014). Mbhiza (2021) emphasized that effective online teaching and learning are required across all South Africa's schooling levels. More importantly, Mhlanga and Moloji (2020) observed that the changes seen in the education sector, triggered by the pandemic, have the potential of moving educational activities to the Fourth Industrial Revolution (4IR), where teaching and learning activities will be predominantly digital as opposed to face-to-face.

Further, this research will therefore contribute to the mentioned gap by paving a path for an online teaching and learning intervention mechanism to be designed and assist where online teaching and

learning is failing to yield the desired outcomes owing to educator ineffectiveness. The following sections review literature on educational technologies and their application in higher education. Thereafter, the research methodology, results, discussion and conclusion of the study respectively are presented.

2. LITERATURE REVIEW

The literature review section is divided into the theoretical background where the information processing model is discussed in relation to online teaching and learning. Thereafter, a discussion is provided on educational technologies and their role in higher education.

2.1 Theoretical background

This study sought to examine educator effectiveness in the use of educational technologies in South Africa's HDIs. Educators' poor use of educational technologies could result in learners failing to engage meaningfully with the learning content, thus defeating the whole idea of active learning. Active learning requires learners to engage, make sense of and apply the learning content to enrich their education experience (Powner & Allendoerfer, 2008). Active learning techniques vary; however, when using educational technologies, learners are required to utilise online platforms to complete learning tasks and other learning-related activities. Active learning stems from the Information Processing (IP) model, a theory of human cognitive processing. The human cognitive processing theory assumes that information is received, stored in the sub-conscious and retrieved when needed (Schunk, 1996).

Traditionally, the IP model is also known as the two-store or dual-memory model (Atkinson & Shiffrin, 1971). The most important issue highlighted by the IP model is a situation when the learner makes a comparison between a new stimulus residing in the short memory versus what the learner already knows that which resides in the long-term memory and then makes the decision whether to add the new stimulus into the long-term memory. Active learning is critical in the sense that it manipulates the manner in which the learner will view the new stimuli, thereby increasing the chances of it being passed on to the long-term memory.

The examination of teacher effectiveness in the use of educational technologies is critical, given the role it plays towards active learning within HDIs. Effective utilisation of educational technologies by educators in HDIs will enrich learner experience, making it easier to compare a new stimulus (new knowledge) versus what the learner already knows, and making the decision to add new knowledge in the long-term memory. The ability to absorb new knowledge, store it, and rely on it for academic purposes is critical if the learner is to achieve the desired learning outcomes. Hence, effective utilisation of online technologies by educators within HDIs is critical to enhance graduate employability prospects of learners. Bester and Brand (2013) concurred and pointed out that learners are able to develop new ideas, create new knowledge, and link emerging information to the real-world circumstances. Such capabilities of learners arguably can contribute towards effective learning that is if the online and teaching platform is well utilised by the educator.

2.2 Educational technologies and higher education

HDIs owned some of the educational technologies that were readily available in the market before the Covid-19 pandemic. However, very few faculty members took the initiative to utilise these

educational technologies during classroom activities until blended learning was enforced through institutional policies after the outbreak of the COVID-19 pandemic. Such reluctance could be attributed to lack of instruction on how faculty members could incorporate educational technologies in classroom settings (Mayberry et al. 2012).

In addition, HDIs trusted the traditional approach to teaching and learning as opposed to virtual classes and this could be attributed to the resource divide which negatively affects tuition at HDIs (Shava, 2022). To determine whether educators within HDIs were effective in the use of educational technologies, four dimensions of online teaching and learning were examined, namely: virtual interaction, unit content migration, online course alignment, and web-based module structure. The paragraphs to follow unpack the mentioned dimensions.

2.3 Virtual interaction

In the domain of online teaching and learning, interaction is a broad term but in simplicity, interaction refers to a direct involvement with someone or something. In the context of this study, this interaction is assumed to be taking place on a virtual online teaching and learning platform. This study views virtual interaction from two dimensions: learner interaction and asynchronous and synchronous interaction (Song, Rice & Oh, 2019). Learner participation and interaction are somehow linked. On the one hand, learner participation can be through assignment submission, or class attendance. On the other hand, it could be interacting with fellow learners, for example, chatting about an assignment or an activity. The chatting (interaction) occurs on the provided online learning platform. Evidence exists suggesting that when educators encourage learners to interact/participate by providing such opportunities, the rate at which learners succeed in online courses increases exponentially (Croxtton, 2014; Hawkins et al., 2013; Joksimović et al., 2015). Research by Goggins and Xing (2016) concurred with the previous assertion as their findings reveal that an increase in the number of interactions significantly predicted achievement of learning outcomes.

2.4 Unit content migration

Unit content migration refers to the educator's ability to transfer learning content from non-online to online sites. The content in question must be rich enough to ensure that achievement of learning outcomes is not compromised (Ashburn & Floden, 2006). Most of the material that the educator would transfer to an online site is more or less similar to that material which would have been utilised in contact sessions. Examples include books published by highly ranked publishers, and journal articles, among others. Teaching material is diverse depending on the discipline (Breslyn & McGinnis, 2012). Therefore, the transfer of material to an online site is not an easy task, as the educator will have to choose the most appropriate content to be uploaded on the correct digital media designed to carry that type of file so that students can easily access it whenever needed.

2.5 Online course alignment

Online course alignment speaks to the educator's ability to create online teaching material, online assessment methods and online teaching activities that support the achievement of set learning objectives by the faculty. According to McTighe and Wiggins (2012), through effective course alignment, students are able to consistently make meaning of the module concepts. In addition,

effective course alignment ensures that there is no information overload leading to the achievement of learning outcomes.

2.6 Web-based module structure

Web-based module structure speaks to the educator's ability to design an online module such that learners find it very simple to navigate. The easier it is for students to navigate, the more user friendly it is. A more user-friendly module site enables students to participate in classroom activities with confidence and further enhances the chances of learning outcomes achievement (Sun, Tang & Zuo, 2020). In their study, Sun et al. (2020) reported that students in China appealed to educators to provide a unified teaching and learning platform with features such as playback and also for educators to issue an appropriate number of formative assessments as opposed to dumping many tasks on the platform. In other words, the online platform must not be too crowded or overloaded with content as it may overwhelm and demotivate the students.

3. RESEARCH METHODOLOGY

The study is quantitative by nature and a positivist research paradigm was pursued. This section elaborates further on the study's research design, sampling method, research instrument, data collection and data analysis.

3.1 Research design

The study is descriptive by design as it is aimed at describing the effectiveness of educators in utilising educational technologies on four dimensions of online teaching, namely virtual interaction, unit content migration, online course alignment and web-based module structure.

3.2 Sampling method

The target population for the study was university students studying in historically disadvantaged institutions (HDIs). Although South Africa has at least six universities categorised as HDIs (Temoso & Myeki, 2022), two of them were selected for the purposes of this research. Proximity to the researcher was the qualifying dimension for participation as resource limitations and the COVID-19 pandemic hindered the researcher from implementing this study at a national scale. Respondents were randomly selected and the determining factor was that a person had to be a registered student in the chosen universities and must have been attending classes virtually. The researcher targeted a large sample resulting in the distribution of 240 questionnaires of which 150 were returned with sufficient information, giving the study a sample size of 150 respondents.

3.3 Research instrument and measures

Gosselin's (2009) Online Teaching Self-Efficacy Inventory was modified to allow students to evaluate educators on how they utilised education technologies. Thus, instead of educators responding to the questionnaire, students were used as respondents. Four dimensions of the Online Teaching Self-Efficacy Inventory were considered to be relevant in the context of HDIs, namely virtual interaction, unit content migration, online course alignment and web-based module structure. The virtual interaction subscale had 10 items and the Cronbach alpha coefficient was derived as .772 indicating that the scale was internally consistent. An example of the scale items reads, "Lecturers are able to manage the pace of facilitating interaction".

The unit content migration subscale had 7 items and its reliability score was derived as .749. An example of the scale item reads, “Lecturers are able to select the appropriate digital media format (PowerPoint, digital photographs, Adobe Flash, etc.) to transfer unit content and materials”.

The online course alignment scale had 11 items and the reliability score was derived as .783. An example of the scale item reads, “Lecturers are able to provide students with detailed feedback about their academic progress”. The web-based module structure sub-scale had 11 items and a reliability of .826 was derived. An example of the scale items reads, “Lecturers are able to adapt the design of online class content to the needs of students (motivation, interest, prior knowledge, etc.)”.

The internal consistency of all four dimensions utilised in this study was above the internal consistency threshold of .7. This is an indication that the scales were all reliable. For all the scales used, they were measured on a five-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree.

3.4 Data collection and analysis

Quantitative data was collected once, thus, a cross-sectional survey was adopted. A self-administered questionnaire was used as a research instrument. The researcher and four trained fieldworkers randomly distributed questionnaires to 240 students who returned to university campus during the controlled student return phases. The study received ethical clearance from the faculty ethics subcommittee (2021/02/IBIKA/FMS) and adherence to prevailing COVID-19 regulations were highly emphasised by the ethics committee. The researcher took the necessary precautions to protect the research team and the respondents. Thus, personal protection equipment and sanitisers were used as prescribed. To make meaning of the data, descriptive statistics were used, and the Statistical Package for Social Sciences (SPSS) version 27 was the software used for data capturing, cleaning, management and analysis.

4. RESULTS AND DISCUSSION

The data revealed that male learners were the dominant group in this study, represented by 56% while 40% were females. The remainder of 4% were in the rather not say category. In terms of race, Africans were the dominant group represented by 98% and the remaining 2% were Coloureds. This result further reinforces the idea that in HDIs, privileged groups such as Whites and Indians are rarely found in the context of South Africa, but they are highly represented in affluent universities whereas Africans are poorly represented there. The distribution of participants by age revealed that 25% of the participants were aged 20 years and below and was dominated by the 21 to 25 years represented by 70%. The 26 years and above age category was the least represented (5%).

A 5-point Likert scale was used to gather primary data and the averages method was used to rate the responses given by learners to determine the effectiveness of educators in their use of online technologies. As mentioned earlier, the Likert scale was anchored by 1 representing strongly disagree, then 2 representing disagree up to 5 representing strongly agree. To interpret the students’ responses with respect to each scale item, a range representing the 5 categories was mathematically derived and the final output revealed that averages between 1.00 and 1.80 represented the strongly disagree category, 1.90 – 2.60 represented disagree, 2.70 – 3.40 represented neutral, 3.5 – 4.20

represented agree and 4.30 – 5.00 represented the strongly agree category. Table 1 provides further details on the intervals and their description.

Table 1: Likert scale range

| Likert scale | Interval | Difference | Description |
|--------------|-------------|------------|-------------------|
| 1 | 1.00 -1.80 | .8 | Strongly disagree |
| 2 | 1.90 – 2.60 | .7 | Disagree |
| 3 | 2.70 – 3.40 | .7 | Neutral |
| 4 | 3.50 – 4.20 | .7 | Agree |
| 5 | 4.30 – 5.00 | .7 | Strongly agree |

Four dimensions were chosen to rate the performance of educators in the use of online teaching technologies, namely virtual interaction, unit content migration, online course alignment, and web-based module structure. The rating results making use of the averages techniques per each scale item are summarised in Table 2.

On the virtual interaction scale, HDI educators were rated better on two items of the scale where they received an average of 3.54 and 3.7 respectively. The V3 item asked learners to rate educators in terms of their ability to encourage learners to ask questions virtually. The V4 item pointed out that lecturers were able to promote student online participation. Students neither agreed nor disagreed with the remainder of the virtual interaction scale; items V2 and V7 rated lowly on this category. The V2 item asked learners to rate whether educators could overcome the influence of adverse student interactions online and this item received an average score of 3.05 (neutral). Similar to the V2 scale item, the V7 item received a 3.05 average score and it required learners to rate whether educators were able to use emotions to enrich communication effectively.

The unit content migration scale had 7 items of which 4 items received average score ratings which placed them in the agree category (UCM1 = 3.65, UCM2 = 3.62, UCM5 = 3.66, and UCM6 = 3.53). On the online content alignment scale, only scale item 11 received a rating of 3.53, that is, the agree category whereas scale items 1 to 10 received ratings which were in the neither agree nor disagree category. Lastly, the web-based module structure had 11 scale items where educators received average ratings that placed them in the agree category on two items only, that is, WMS1 and WMS4 with scores of 3.51 and 3.54 respectively. The other nine scale items were rated in the neither agree nor disagree category.

Table 2: Online educational technologies usage ratings of HDIs educators

| Code | Scale item | Average |
|------|--|---------|
| | Virtual interaction scale | |
| VI1 | Get students to work together in online classes. | 3.42* |
| VI2 | Lecturers are able to overcome the influence of adverse student interactions online. | 3.05* |
| VI3 | Lecturers are able to encourage students to ask questions. | 3.70 |
| VI4 | Lecturers are able to promote online student participation. | 3.54 |
| VI5 | Lecturers are able to project a positive virtual social presence (the perception of being real). | 3.23* |
| VI6 | Lecturers are able to effectively express emotion within the online environment. | 3.05* |
| VI7 | Lecturers are able to use emotion to effectively enrich communication. | 3.17* |
| VI8 | Lecturers are able to adopt a teaching style that allows for the facilitation of learning through guidance. | 3.31* |
| VI9 | Lecturers are able to manage the pace of facilitating interaction. | 3.24* |
| VI10 | Lecturers are able to adequately convey their availability for consultations making use of online platforms. | 3.37* |

| | Scale item | Average |
|-------------------------------------|--|----------------|
| Unit content migration scale | | |
| UCM1 | Lecturers are able to prepare the teaching materials to use online. | 3.65 |
| UCM2 | Lecturers are able to select the appropriate digital media format (PowerPoint, digital photographs, Adobe Flash, etc.) to transfer unit content and materials | 3.61 |
| UCM3 | Lecturers are able to select the appropriate online method to effectively convey unit content once used in traditional style (lecture of face-to-face) classrooms. | 3.47* |
| UCM4 | Lecturers are able to transfer lecture presentations used in face-to-face style units to online formats. | 3.39* |
| UCM5 | Lecturers are able to transfer assignments and assessments (such as exams) used in face-to-face style units to online formats. | 3.66 |
| UCM6 | Lecturers are able to determine the appropriate resources (i.e., technological, personnel, software, etc.) to assist with transferring unit materials from face-to-face to online formats. | 3.53 |
| UCM7 | Lecturers are able to manage the time needed to transfer unit content from face-to-face to online formats. | 3.43* |
| Online course alignment | | |
| OCA1 | Lecturers are able to evaluate the degree to which learning outcomes have been met. | 3.4* |
| OCA2 | Lecturers are able to use strategies to increase students' remember content covered online. | 3.26* |
| OCA3 | Lecturers are able to provide students with detailed feedback about their academic progress. | 3.41* |
| OCA4 | Lecturers are able to determine the most appropriate evaluation method for a particular unit. | 3.34* |
| OCA5 | Lecturers are able to clearly articulate the learning goals that students are expected to achieve. | 3.43* |
| OCA6 | Lecturers are able to connect unit assignments with the stated learning outcomes. | 3.28* |
| OCA7 | Lecturers are able to accurately assess the depth of students' learning. | 3.29* |
| OCA8 | Lecturers are able to accurately assess the depth of students' level of engagement. | 3.05* |
| OCA9 | Lecturers are able to engage students from a variety of cultural backgrounds. | 3.28* |
| OCA10 | Lecturers are able to engage students who have a wide variety of familiarity with online learning. | 3.22* |
| OCA11 | Lecturers are able to use written instructions to facilitate student engagement in online units. | 3.53 |
| Web-based module structure | | |
| WMS1 | Lecturers are able to adapt the design of online class content to the needs of students (motivation, interest, prior knowledge, etc.). | 3.51 |
| WMS2 | Lecturers are able to design online module content in accordance with the requirements of South African Qualifications Authority (SAQA). | 3.29* |
| WMS3 | Lecturers are able to design online module content that is easy for students to navigate. | 3.41* |
| WMS4 | Lecturers are able to create appropriate links to module content pages and materials. | 3.54 |
| WMS5 | Lecturers are able to design a unit that is representative of my institution's mission, goals and objectives. | 3.37* |
| WMS6 | Lecturers are able to design module content that address students' concerns and apprehensions about module content. | 3.33* |
| WMS7 | Lecturers are able to design a module content that another teacher could teach. | 3.25* |
| WMS8 | Lecturers are able to manage the time requirements needed to develop courses. | 3.29* |
| WMS9 | Lecturers are able to design module content that meet regulatory agency accreditation guidelines. | 3.341 |
| WMS10 | Lecturers are able to use digital media to create module content. | 3.47* |
| WMS11 | Lecturers are able to create module learning content that is consistent and structured. | 3.42* |

* scale item(s) with ratings below the agree and strongly agree categories

The descriptive results in the form of means per scale item informs us whether educators in HDIs effectively use online technologies. Based on the findings, with respect to the virtual interaction scale, only two items were rated in the agree category and the other eight scale items fell in the neither disagree nor agree category. Given this finding, it is evident that HDI educators are able to make students interact virtually, which increases their chances to pass online modules. This is line with research which found that when educators are able to make students interact virtually among

one another, the rate at which they are likely to pass online courses increases significantly (Croxtton, 2014; Goggins & Xing, 2016). The results further reveal that none of the HDI educators were rated in the strongly agree category (4.30 – 5.00), on the virtual interaction scale. In other words, with the continued adoption of online educational technologies and educator support on the use of online educational technologies, chances are that HDI educators will be able to enhance student learning through virtual interaction.

The findings with regard to the unit content migration show that the majority of students agree that HDI educators are effective in the use of online educational technologies and this ensures that meaningful learning is achieved. Unit content migration is an important task and when done correctly, it ensures that learners are provided with all the relevant learning material they need with respect to the qualifications they are studying for. This is in line with literature, which indicates that the ability of educators to migrate content from non-online to relevant online platforms enhances student learning through online educational technologies (Ashburn & Floden, 2006).

With respect to the online course alignment scale, the results reveal that HDI educators are able to link the learning outcomes and course components, assess the depth of student learning, implement strategies to ensure students remember content, and to provide students with detailed feedback among other important tasks associated with it. This is important as research revealed that effective course alignment plays a critical role in the achievement of learning outcomes by students (McTighe & Wiggins, 2012).

Results with respect to the web-based module structure also reveal that HDI educators are able to design the learning platform in such a way that it is user friendly. This is critical in the sense that a non-user-friendly learning platform defeats the goals of teaching and learning (Sun et al. 2020). The overall findings of this research are in line with the body of literature which indicates that most online teaching and learning within HDIs only got underway as a result of the Covid-19. A study by Suresh, Priya and Gayathri (2018) confirms that before the pandemic, the majority of universities utilised e-learning as an additional mode of educational delivery. To a greater extent this explains why the majority of the universities globally faced many challenges in the full implementation of e-learning as a major education delivery, including HDIs in South Africa. Major problems experienced were access to online educational technologies and the ability of educators to effectively deliver online courses (Coman, Țîru, Meseşan-Schmitz, Stanciu & Bularca, 2020). In addition, this explains why educators could not receive an outright rating of effective in the use of online educational technologies as they lacked prior experience and the know-how. Literature also pointed out that before the Covid-19 pandemic, most universities had no proper infrastructure to support online teaching and learning. This may have influenced educators to invest little time and effort in the use of existing online teaching technologies. To a certain degree, it can be argued that such acts deprived them of learning opportunities to gain the expertise and experience on how to fully utilise online educational technologies and render them highly effective. However, the little opportunities they had did provide them with the basics on the use of online educational technologies as observed from the ratings they received from students across four dimensions of online teaching and learning. Overall, making use of their basic understanding of online educational technologies, HDI educators were able to deliver online courses as observed from the findings of this study.

4.1 Implications to theory and managerial practice

Educator effectiveness in the use of online technologies is critical as far as active learning is concerned. This was emphasised by the IP model which advocates for the ability of educators to add new stimulus, that is, addition of new knowledge to the learner's short memory which will then be transferred to the long-term memory, that is, if a learning discrepancy has been confirmed. Educators within HDIs can enhance their effectiveness in the use of online technologies when HDIs continue to invest in training and continued provision of other online teaching-oriented support mechanisms for educators at individual level. These could be in the form of short courses, for example the Online Teaching with Technology module now on offer at various universities in South Africa. HDIs can finance such courses on behalf of educators given that blended learning is now a widely adopted teaching and learning approach in South Africa. In addition, universities and stakeholders in the higher education sector should collaborate, share experiences and online educational technologies to ensure that online teaching and learning within HDIs can be enhanced. More importantly, this will ensure that the technology gap that exists between South Africa's universities can be reduced.

4.2 Future research

Future research can focus on finding ways in which HDIs and affluent universities can collaborate to ensure that educators both from HDIs and from affluent universities can work together to ensure online teaching practices are on par across South African universities.

5. CONCLUSION

This study investigated the use of online educational technologies within HDIs in South Africa. Educators were rated across four dimensions of online teaching and learning, namely virtual interaction, unit content migration, online course alignment and web-based module structure. The findings reveal that educators within HDIs were able to make use of online educational technology to delivery online courses. The study is important to all stakeholders who are concerned about the use of educational technologies within HDIs to enhance student experience given the existing resource gap between South African universities. Literature reviewed and the findings of the study do provide evidence that with educational technologies and sufficient online infrastructure within HDIs, student experience can be enhanced.

THE IMPACT OF STRATEGIC AGILITY ON BUSINESS PERFORMANCE

S. Govuzela

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

Most organisations are struggling to continuously adjust and adapt key decisions to the challenging external environment. Business executives are struggling to design firms that are efficient to drive performance in the short run and flexible enough to sustain business performance over the long run. An extensive literature review regarding business performance, strategic agility and its four sub-components (collaborative innovation, technology capability, organisational learning and internal alignment) was performed. This study aimed to investigate the impact of strategic agility on the business performance. This aim was achieved by an extensive literature review, which revealed that strategic agility positively impacts business performance. The study showed that strategic agility and its four sub-components (collaborative innovation, technology capability, organisational learning and internal alignment) can assist the organisations to continuously adjust and adapt key decisions to the challenging external environment. The study concludes that strategic agility has a positive impact the business performance. Strategic agility and its four sub-components (collaborative innovation, technological capability, organisational learning and internal alignment) assist organisations to respond well to environmental changes. In view of the study's results, it is thus recommended that organisations and business executives work on improving their strategic agility and its four sub-components (collaborative innovation, technological capability, organisational learning and internal alignment) to enhance their business performance.

Keywords: Strategic agility, collaborative innovation, technological capability, organisational learning, internal alignment, business performance

1. INTRODUCTION

Most organisations are struggling to continuously adjust and adapt key decisions to the challenging circumstances of the external environment. Business executives are struggling to design firms that are efficient enough to drive performance in the short run and flexible enough to sustain organisational performance over the long run. The new norm in industry requires organisations to have a remarkable amount of agility in order to survive in the business environment. Various factors such as technology, innovation, industry trends and increased competition lead to a higher need for securing competitive advantage over the competitors. Organisations can use strategic agility to identify and react to the changes and challenges in the business environment.

The aim of this paper is to investigate the impact of strategic agility on business performance. This paper also aims to help the business executives to design organisations that are efficient enough to successfully drive performance in the short run and flexible enough to sustain organisational performance over the long run. This paper will use the literature to enrich the knowledge of organisations and business executives on strategic agility.

2. LITERATURE REVIEW

2.1 The Concept of Strategic Agility

According to Lungu (2020), strategic agility is defined as the ability of the organisation to respond fast to the changes in the business environment, adapt to it and take necessary actions to control uncertainty. Winby and Worley (2014) define strategic agility as the ability of the organisation to continuously adjust and adapt key decisions to the challenging circumstances of the external environment and thus nurture value creation. According to Ofoegbu and Akanbi (2012), strategic agility is the ability to continuously and adequately adjust and adapt, in the appropriate time, the strategic direction in core business in relation to changing circumstances.

2.2 Key Capabilities Enabling Strategic Agility

Three main dimensions in strategic agility are strategic sensitivity, leadership unit and resource fluidity (Mukerjee, 2014). Strategic sensitivity includes leadership actions such as anticipating with foresight, experimenting and corporate venturing, distancing to gain perspective, abstracting to concepts and models and reframing to imagine and generate new business models. Leadership unity encompasses actions designed to create bond and trust within the leadership team. Resource fluidity is a company's ability to reform business models and reallocate resources rapidly and it is divided into three main clusters of tools, which are mobilising capital resources, mobilising people and knowledge and creating a modular structure (Mukerjee, 2014).

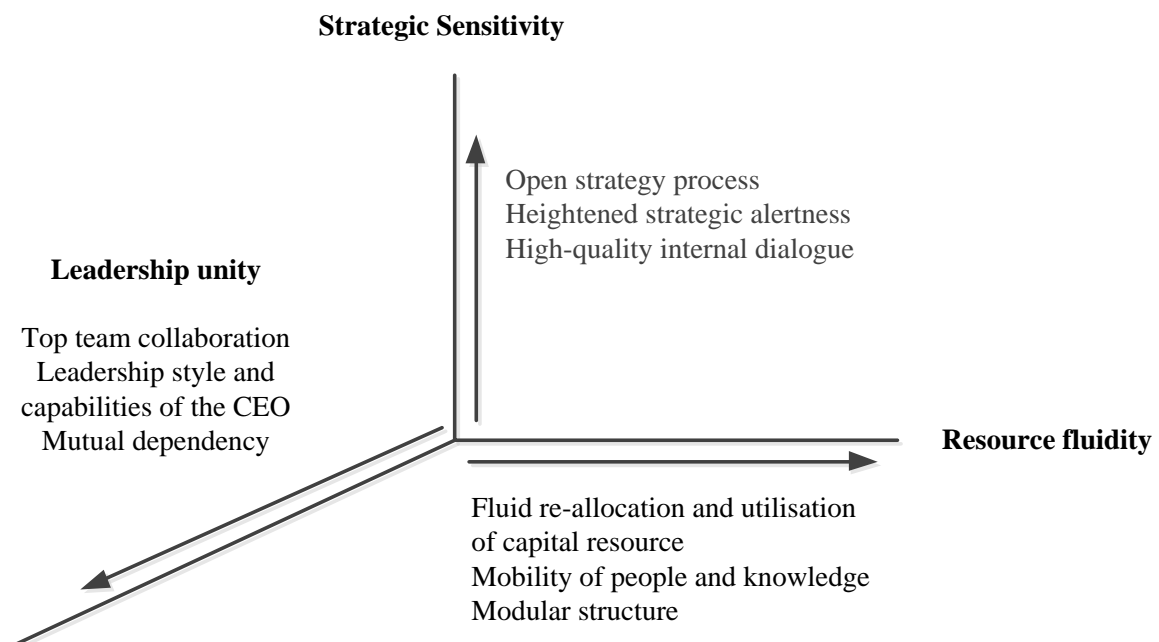

Figure 1. Key Capabilities Enabling Strategic Agility

Source: Doz (2011)

2.3 The Importance of Strategic Agility

The importance of applying strategic agility to organisations is one of the fundamental requirements for success. It is the guarantor of the organisation's survival and continuity (Abusalma, 2021). Strategic agility is the key to success in a dynamic and fast-changing business

environment (Halalmeh, 2021). Ofoegbu and Akanbi (2012) indicate that strategic agility can bring about organisations that can produce the right products and services at the right place at the right time at the right price and for the right customers. Di Minin, Frattini, Bianchi, Bortoluzzi and Piccaluga (2014) state that strategic agility's main goal is to integrate diverging strategic objectives.

Strategic agility is most important for organisations in which the business environment is rapidly changing and this change has a complex nature (Dabiri & Gholami, 2015). A survey by McKinsey found that nine out of ten executives agreed that strategic agility is critical to both business success and growth (Chandler Macleod Group Limited, 2011). Strategic agility is an applied methodology that yields business performance (Salih & Alanaji, 2014). The largest performance impact is on customer satisfaction, which in turn, contributes to improved bottom line financial performance (DeGroot & Marx, 2013). Strategic agility has various sub-components such as collaborative innovation, technological capability, organisational learning and internal alignment (Chen (2013).

2.4 Collaborative Innovation

The definition of collaborative innovation is “a distributed innovation process based on purposively managed knowledge that flows across organisational boundaries, using pecuniary and non-pecuniary mechanisms in line with each organisation's business model” (Chesbrough & Bogers, 2014). Collaborative innovation is a two-way process in which companies have an inbound process in which they bring ideas, technologies, or other resources needed to develop their own business and an outbound process in which they out-licence or sell their ideas, technologies and other resources (Lindgaard, 2011). Collaborative innovation is defined as the use of purposive inflows and outflows of knowledge to accelerate internal innovation and to expand the markets for external use of innovation respectively (Jean-Claude, 2015).

Collaboration innovation is often divided into two core processes which are inbound and outbound collaboration innovation processes (Jean-Claude, 2015). Some authors consider a third process called coupled collaboration innovation (Mazzola, Bruccoleri & Perrone, 2012). Coupled collaboration innovation is co-innovation with complementary partners that combines the inbound with the outbound processes to bring the ideas to market and in doing so jointly develop and commercialise innovation. Linking both technology exploration and exploitation increase the global value orchestration (Lindgreen, Hingley Gant & Morgan, 2012).

2.5 Technological Capability

Technological capability is defined as the ability of the firm to manage and generate technological changes (Diyamett & Mutambla, 2014). It is the ability to innovate and to make effective use of technological knowledge in assimilating, using, adapting and changing existing technologies (Noh, Kim & Jang, 2014). It refers to a firm's ability to develop and use substantial technological resources (Su, Peng, Shen & Xiao, 2013). Technological capability is defined as the accumulated knowledge, skill expertise and organisational base which enables the firm to acquire, develop and use technology to achieve competitive advantage (Lopez-Salazar, Lopez-Moteo & Molina-Sanchez, 2014).

Technological capability is composed of two broad elements, namely, embodied and disembodied. The embodied elements of technological capability are those that involve the human aspect. They

include skills, knowledge, attitude and aptitude. The second is the non-embodied/disembodied elements. These are the part of the technological capabilities that are codified and can easily be transferred among users, which include equipment and software (Sobanke, Ilori & Adegbite (2012). Technological capability is categorised into three major levels depending on the complexity of the knowledge and therefore ease of achievement (Diyamett & Mutambla, 2014).

2.6 Organisational Learning

Organisational learning is defined as a process of inquiry through which members of the organisation develop shared values and knowledge based on their own experience and that of other (Herstein, 2011). It is defined as the process of improving actions through better knowledge and understanding (Ranjbar & Absalan, 2015). Organisational learning is a process of creating and transferring knowledge within an organisation (Zafar, Hafeez & Shariff, 2016).

The concept organisational learning describes the internal capacity of the organisation to learn from experience, to examine and adopt new ideas and transform them into policy and action plans to obtain competitive advantage (Herstein, 2011). Organisational learning is about the ability of the organisation to apply accurate and appropriate management practices, its structure as well as the procedures to enhance, facilitate and encourage learning (Shoid & Kassim, 2012).

2.7 Internal Alignment

Internal alignment deals with specifying how harmoniously the different departments of an organisation work together and how tightly their activities are coordinated (Pardo, Ivens & Wilson, 2013). Internal alignment is a group process related to shared comprehension among team members to attain organisational objectives (Puente-Palacios, Moreira, Puente & Lira, 2015). Internal alignment is the state of collaboration that exist among departments (Teixeira, Koufteros & Peng, 2012).

The internal alignment concept builds on the underlying hypothesis that higher degree of internal is associated positively with coordination and cooperation in the implementation of the strategy and hence with business performance (Mirzaei, Fredriksson & Winroth, 2016). Prior studies have conceptualised internal alignment broadly as the fit between a firm's external environment and its strategic orientation, organisational structure and processes (Ravasi & Phillips, 2011). The conceptualisation of internal alignment suggests that the extent of internal alignment results from skill rather than luck. This perspective is especially useful for organisational leaders as it profits an institutional orientation of internal alignment (Alagaraja & Schuck, 2015).

2.8 The Concept of Business Performance

The definition of business performance and its measurements continues to challenge scholars due to its complexity (Santos & Brito, 2012). Mostly, researchers use the term business performance to express the range of measurements of transactional efficiency and input and output efficiency (Shahzad, Luqman, Kahn & Shabbir, 2012). Irrespective of the differences among researchers on the definition, they agree that it is mostly tied in with arithmetic measures of success (Eniola & Entebang, 2015).

Nowadays, the performance of the business is the first thing to be evaluated by investors around the world (Al-Marari, Al-Swidi & Fadzil, 2014). Scholars have found that there are many variables

that affect business performance such as entrepreneurial orientation, information technology, strategy and others (Guo & Cao, 2012). Even if there are many various variables affecting business performance, but leadership style and innovative factors have a considerable effect on business performance (Erdem, Gokdeniz & Met, 2011).

Business performance has been measured in accounting terms such as profit, cost and market share (Al-Ansari, 2014). However, it should be measured using both financial and non-financial terms to enable efficient strategic decision-making where non-financial terms focus on the long-term success of the firm, customer satisfaction, internal business processes efficiency and innovation (Avci, Madanoglu & Okumus, 2011).

3. CONCEPTUAL FRAMEWORK AND SUMMARY OF PREMISES

The study tested the conceptual framework illustrated in Figure 1 which shows that technology capability, collaborative innovation, organisational learning and internal alignment are the sub-components of strategic agility.

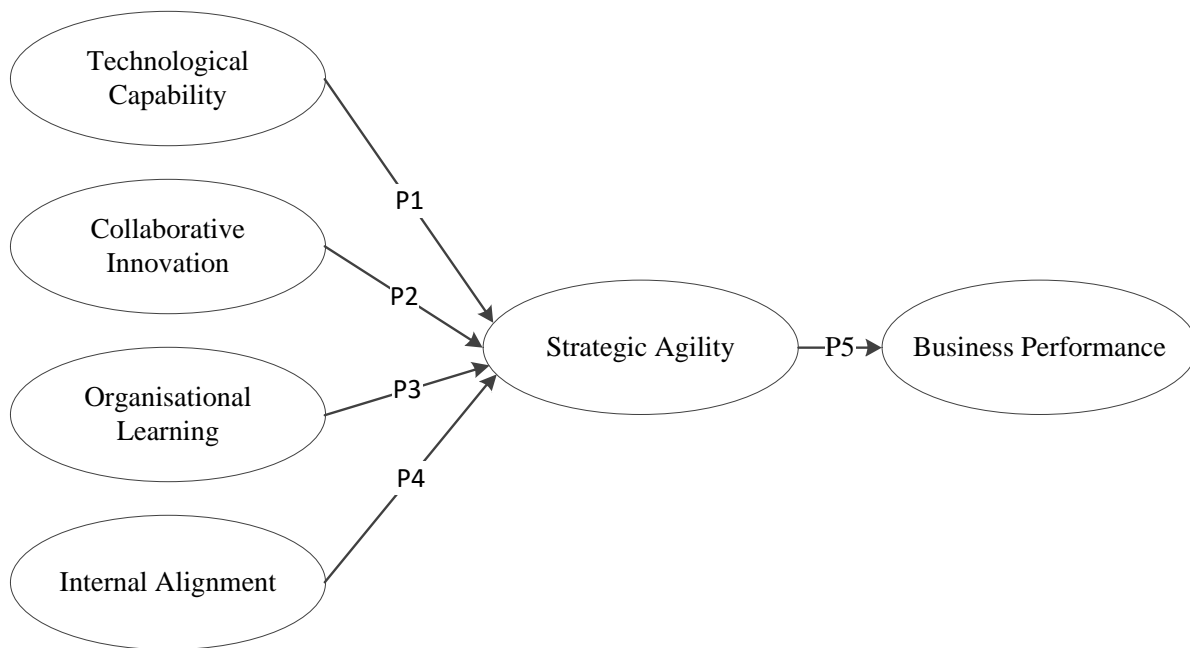

Figure 2. Conceptual Framework for Strategic Agility and Business Performance

Source: Govuzela and Mafini (2019)

The study also focused on testing the following premises, as indicated in the conceptual framework:

- P1: Strategic agility has a positive impact on technological capability
- P2: Strategic agility has a positive impact on collaborative innovation
- P3: Strategic agility has a positive impact organisational learning
- P4: Strategic agility has a positive impact internal alignment
- P5: Strategic agility positive has a positive business performance

The purpose of the study was to explore the extent to which strategic agility has an impact on business performance.

4. PROBLEM INVESTIGATED

The impact of strategic agility on business performance was investigated.

5. RESEARCH OBJECTIVES

The following theoretical objectives were formulated:

- 5.1 To carry out a literature study on strategic agility (and its four sub-components, collaborative innovation, technological capability, organisational learning and internal alignment).
- 5.2 To carry out a literature study on business performance.

6. RESEARCH METHODOLOGY

6.1 Research Design

Research design refers to a framework for conducting a research project. It specifies the details of the procedures necessary for obtaining the information needed to structure and solve research problems (Hove, 2012). A research design is defined as a blueprint for the collection, measurement and analysis of data, based on the research questions of the study (Sekeran & Bougie, 2010). It can initiate the information needed, the conceptual model, selected method, sampling method, sample size, measurement procedure and data analysis process, which plans and links collected data to the initial research question in the research study (Al-Ansari, 2014).

A qualitative research method was used in this study. Busetto, Wick and Gumbinger (2020) define qualitative research as the study of the nature of phenomena, including their quality, different manifestations, the context in which they appear or the perspective from which they can be perceived, but excluding their range, frequency and place in an objectively determined chain of cause and effect. Qualitative research generally includes data in the form of words rather than numbers.

6.2 Data Collection

This investigation used a document study to collect data on business performance, strategic agility and its four sub-components (collaborative innovation, technological capability, organisational learning and internal alignment). Data was collected from articles, dissertations, internet, theses and textbooks. Electronic databases such as Emerald, Science Direct, EBSCO-Host, Nexus, Sabinet and Sage were used as sources of data. Keywords were used to search for the relevant data in this document study.

6.3 Data Analysis

To analyse means to break down a whole into its components or constituent parts. Through assembly of the parts, one comes to understand the integrity of the whole (Onwuegbuzie, Leech & Collins, 2012). Analysis of literature takes one of two forms: within-study literature analysis or a between-study literature analysis. A within-study literature analysis involves analysing the contents of a specific work. In its most rigorous and comprehensive form, a within-study literature analysis does not merely involve analysing the findings of a study or the major premise used in a non-empirical work. Rather, optimally, it involves analysing every component of the work, including the title, literature review section, conceptual framework/theoretical framework,

procedures used, results section and discussion section (Onwuegbuzie, Leech & Collins, 2012). A within-study literature analysis was employed in this study to analyse the data collected. Keywords were also utilised to analyse the data in this document study.

7. RESULTS

This study examined the relationship between strategic agility and business performance. This aim was achieved by developing five premises. This section discusses the results of each of these premises.

7.1 Strategic Agility and Technological Capability

The first premise (P1) suggests a significant positive relationship between strategic agility and technological capability (Govuzela & Mafini, 2019). Literature showed that strategically agile firms can manage and generate technological changes. They use technological knowledge effectively in assimilating, using, adapting and changing existing technologies. Strategically agile firms can develop and design new products, new processes and more effectively operate the equipment, or resources needed to produce managerial technique revolution including skills, knowledge and experiences as well as institutional structures and ties. Strategically agile firms jointly mobilise different scientific resources and individual technicians, which allows the development of products or innovative and successful production processes, serving the implementation of competitive strategies that create value given certain environmental conditions. Thus, strategic agility serves as a driver for technological capabilities within organisations (Govuzela, 2018).

7.2 Strategic Agility and Collaborative Innovation

The second premise (P2) suggests that there is a positive relationship between strategic agility and collaborative innovation (Govuzela & Mafini, 2019). Literature review revealed that strategically agile firms use a two-way process in which they have an inbound process to bring in ideas, technologies, or other resources needed to develop their own business and an outbound process in which they out-licence or sell their own ideas, technologies and other resources. Strategically agile firms use purposive inflows and outflows of knowledge to accelerate internal innovation and to expand the markets for external use of innovation respectively. Traditionally, new technologies were mostly developed in-house. As they became more complex and requested a broad portfolio of relevant knowledge, that a single firm could not have, collaboration with external partners (suppliers, customers and competitors) gained the upper hand. Hence, strategic agility leads to improved collaborative innovation within organisations (Govuzela, 2018).

7.3 Strategic Agility and Organisational Learning

The third premise (P3) suggests that there is a positive relationship between perceived strategic agility and organisational learning (Govuzela & Mafini, 2019). Literature review discovered that strategically agile firms use a process of inquiry through which members of the organisation develop shared values and knowledge based on their own experiences and that of others. Agile organisations make use of learning processes at the individual, group and system level to transform the organisation continuously in a direction that is increasingly satisfying to its stakeholders. They also focus on proper learning, which leads to specified results such as an increase in the

organisation's intelligence, the improvement of its knowledge base, the increase in shareholders' satisfaction, the increase in the organisation's long-term adaption ability, improvement of organisational productivity, more effective activities for customers and partners and the development of competitive advantage. Accordingly, strategic agility leads to better organisational learning within organisations (Govuzela, 2018).

7.4 Strategic Agility and Internal Alignment

The fourth premise (P4) suggests that there is a positive relationship between strategic agility and internal alignment (Govuzela & Mafini, 2019). Literature review indicated that strategically agile firms implement the process of achieving unity of effort among the various subsystems in the accomplishment of the organisation's tasks. In agile organisations, the different departments work together and tightly coordinate their activities for the achievement of organisational objectives. Agile firms employ a set of commitments, policies, strategies, procedures, behaviours and systems that support integrated customer decision-making based on suppliers' commercial and ethical commitment and performance. Their employees have an agreement of various levels on the organisation's most important goals. This validates that strategic agility is an important antecedent to internal alignment within organisation (Govuzela, 2018).

7.5 Strategic Agility and Business Performance

The fifth premise (P5) suggests that there is a positive relationship between strategic agility and business performance (Govuzela & Mafini, 2019). Literature review indicated that strategically agile firms have the operational ability to satisfy the desires of the company's major shareholders. They utilise their resources (such as knowledge, people and raw materials) to achieve organisational goals effectively and efficiently. Strategically agile firms can attain their goals by using resources in an efficient and effective manner. They use a set of financial and non-financial indicators, which offer information on the degree of achievement of objectives and results. Agile firms achieve their performance objectives based on the constraints imposed by the limited resources. In this context, profit is one of the many indicators of business performance. Therefore, strategic agility within organisation is an important contributor to business performance (Govuzela, 2018)

8. CONCLUSIONS

This document study investigated the impact of strategic agility on business performance. The results of the study indicate that strategic agility has positive influence on business performance. For this reason, the study concludes that strategic agility has positive impact on business performance. The study also concludes that strategic agility and its four sub-components (collaborative innovation, technological capability, organisational learning and internal alignment) assist organisations to respond well to environmental changes. Therefore, it can thus be concluded that strategic agility positively and significantly influences business performance.

9. RECOMMENDATIONS

The results and conclusions of this study indicate that strategic agility and its four sub-components (technological capability, collaborative innovation, organisational learning and internal alignment) contribute positively towards business performance. Strategic agility assists organisations to

respond well to unexpected challenges and environmental dynamics. It is thus recommended that organisations and business executives should work on improving their strategic agility to enhance their business performance.

- To maintain satisfactory technological capability, organisations and business executives should:
 - Adopt technology-driven systems such as just-in-time, value analysis, concurrent engineering and modular design systems.
 - Invest in upgrading production, information and inventory management systems.
- To maintain satisfactory collaborative innovation, organisations and business executives should:
 - Upgrade process/product design by investigating customer needs in the product development process.
 - Promote collaboration among major functions from the planning stage.
- To maintain satisfactory organisational learning, organisations and business executives should:
 - Provide an optimal working environment in which best performance practices can be disseminated.
 - Promote interdisciplinary training and team-based activities.
- To maintain satisfactory internal alignment, organisations and business executives should:
 - Align functional strategies with business strategy.
 - Align operational strategy with other functional strategies as well.
- To maintain satisfactory strategic agility, organisations and business executives should:
 - Be flexible in product mix or variety.
 - Maintain short cycles in product design and innovation.
- To maintain satisfactory business performance, organisations and business executives should:
 - Enhance return on investment by employing the skills and information needed to identify feasible investment projects.
 - Boost sales growth by having the ability to achieve market leadership.

THE ROLE OF HOUSE PRICES IN THE MONETARY POLICY TRANSMISSION MECHANISM OF SOUTH AFRICA

T. Ncanywa

Walter Sisulu University, Butterworth, South Africa

Abstract

Markets for residential property that include houses and loans secured on them are the most important assets and liabilities of the financial sector. Developments in house prices are a major part of the asset price information relevant for monetary policy. The paper examines the role of house prices in the monetary policy transmission mechanism in South Africa. The paper employs the Vector Error Correction Model (VECM) and Granger causality tests that incorporate quarterly data from 1990 to 2020. The VECM model comprises the domestic interest rate, consumer price index (inflation), GDP (real GDP at constant prices), and real house prices. Based on the order of the significance of the tests, the detection of causality between these variables arises, which indicates that house prices play a significant role in interest rates, and the ‘other asset price channel’ is the possible channel of monetary transmission. Inflation targeting of the monetary policy, transparency, and accountability have improved immensely, and further improvements are in prospect. It is recommended that this channel can be followed to evaluate the stance of the monetary policy, especially the role shown by house prices.

Keywords: Asset prices; house prices; monetary policy transmission mechanism; Vector Error Correction Model; Granger causality

1. INTRODUCTION

Monetary policy is a tool used by a national government of a country to influence its economy (Bernanke, Laubach, Mishkin & Posen, 2018; Wang, Lucey, Vigne, & Yarovaya, 2021). The government influences the overall economic activity level by allowing the monetary authorities to control the supply and availability of money. The monetary policy measures are usually aimed at influencing the quantity of money or the rate of interest to achieve its goal (Bernanke et al., 2018; Husna, Atika, Wahyudi, & Soemitra, 2021). The goal of monetary policy is macroeconomic stability which implies price stability, high employment, economic growth, interest rate stability, or stability of foreign exchange markets. However, the main goal of monetary policy in South Africa is price stability, relating to a stable and low inflation rate (Greenwood & Hanke, 2021).

The monetary policy framework implemented by the South African Reserve Bank (SARB) is an inflation-targeting framework. The SARB uses the repo rate as an instrument to target inflation, which is the rate the SARB charges for borrowed cash reserves (De Angelis, 2005; Seidman-Makgetla, 2021). The repo rate instrument has a direct effect on other variables in the economy, as it affects the demand and supply of goods and services (Wang et al., 2021; Husna et al., 2021). Through the assortment of relay mechanisms referred to as the transmission mechanism of monetary policy, several economic variables, including inflation, are affected (Fikri, 2018; Twinoburyo & Odhiambo, 2018).

To be successful in implementing monetary policy, the monetary policy practitioners should have an accurate assessment of the timing and the effect that their policies have on the economy, thus requiring an understanding of the mechanisms through which monetary policy affects the economy (Rosenberg, 2019). The monetary policy transmission mechanism is a complex process whereby the monetary policy stance is transmitted to achieve the goal of monetary policy (Song, Yang, Yu & Zhao, 2021). When the central bank decides to influence the change in the repurchase rate, it sets in motion a series of economic events which are referred to as the transmission mechanism of monetary policy. The literature suggests that monetary policy is transmitted through four main channels (Song, et al., 2021; Greenwood & Hanke, 2021). These channels include interest rate effects, exchange rate effects, asset price effects, and the credit channel. The focal point of this paper is the asset price channel, and it is measured by the role played by house prices.

Various asset prices are linked to the monetary policy transmission mechanism. These assets include stocks, bonds, housing, and foreign exchange. Mishkin (2001; 2011) surveys the transmission mechanisms of monetary policy beyond the standard interest rate channel by focusing on how monetary policy affects the economy through asset prices. Many studies have mainly focused on different channels of the South African transmission mechanism through which monetary policy affects the economy. For instance, Taguchi, Sahoo & Nataraj (2015) looked at capital flows on asset prices; Gumata & Ndou (2017) on exchange rate channels; Ducastel & Anseeuw (2017) on agriculture as an asset class; Ndou, Gumata & Ncube (2018) on exchange rate shocks. In addition, some studies outside South Africa investigated asset prices other than house prices, for example, Husna et al. (2021) in Indonesia and Song et al. (2021) in China. The novelty of this paper is to fill the gaps in the literature by focusing on the asset price channel, which deals with the role of house prices on the monetary economy. Moreover, the contribution of the house price channel can assist policymakers to be conscious of the consequences of the global financial crises of 2007-2008 as they emanated from shocks in house prices (Dlamini, & Ngalawa, 2022). Given the role that house prices play in the transmission mechanism, central banks have often been tempted to use them as targets of monetary policy, which is likely to lead to worse economic outcomes and might even erode the support for their independence (White, 2012; Rosenberg, 2019).

Literature debates in South Africa that include house prices do not focus on the role played on monetary policy, and therefore, no focus on the asset price channel. For instance, Aye, Balcilar & Gupta (2013) found a non-linear relationship between house and stock prices in South Africa in their non-parametric analysis. Apergis, Simo-Kengne & Gupta (2015) used a clustering procedure to discover a heterogeneous relationship between house prices and club convergence in nine South African provinces. There is a weak relationship in emerging economies including South Africa between house prices and some macroeconomic indicators (Twinoburyo & Odhiambo, 2018; Tita & Opperman, 2021). For example, Twinoburyo & Odhiambo (2018) documented an inconclusive relationship between monetary policy and economic growth in developing countries including South Africa. Tita and Opperman (2021) investigated the role played by house prices on household income per capita and realized that home ownership can reduce inequalities and increase wealth. Kim & Mehrotra (2022) concluded a weak association between macro-prudential policy and credit shocks. These debates indicate a gap in South African literature on studies that focused on the role of house prices on monetary policy hence this paper could contribute to documenting the possibility of the asset price channel

Homes and loans secured on them are respectively the most important assets and liabilities of the financial sector (Bernanke et al., 2018; Rosenberg, 2019; Dlamini, & Ngalawa, 2022). Developments in house prices and activity are, therefore, a major part of the asset price information relevant for monetary policy. Consider, for example, some aspects of the relationship between house prices and consumer expenditure. Higher house prices increase the (gross) wealth of homeowners, and greater wealth tends to lead to higher consumer spending (Dong, Chang, Wang & Liu, 2021; Tita & Opperman, 2021). Indeed, it may be that increases in housing wealth tend to influence consumption more than increases in financial wealth. This shows the importance of the asset price channel, especially to open economies where the flow of capital can affect the domestic behavior of monetary policy variables including house prices (Gilbert, Scotti, Strasser & Vega, 2017).

Houses can be used as collateral for household borrowing through mortgage equity withdrawal. There are also direct effects of house prices on inflation measures than, say, pension fund wealth (Berger, Guerrieri, Lorenzoni, & Vavra, 2018). House prices may also reflect other influences on consumption, such as the level of, and uncertainty about, expected future income from employment. Moreover, activity in the housing market, which tends to be greater when prices are rising, can directly affect demand for consumer durables (Dong et al., 2021). This indicates the importance of studying the asset price channel through the role house prices play in the monetary policy transmission mechanism. In addition, Dlamini & Ngalawa (2022) discovered that monetary policy is not a significant contributor to house prices, allowing this paper to investigate if there is directional causality in this relationship. Following the discussions above, the following questions come to mind; what is the role of house prices in the monetary transmission mechanism in South Africa over these years? Hence, it is imperative to examine the role of house prices in the monetary policy transmission mechanism in South Africa. The paper is structured as follows; this section is followed by a literature review, then methodology, results and discussions, conclusions, and recommendations.

2 LITERATURE REVIEW

2.1 Theoretical literature

This section aims to review theoretical literature on the conduct of monetary policy and its effect on the channels of monetary policy through the monetary policy transmission mechanism. The adopted theory focuses on the fact that the Keynesians view the monetary transmission mechanism as the route by which changes in monetary policy are related to changes in output, employment, prices, and inflation (Del Negro, Giannoni, & Schorfheide, 2015; Fikri, 2018; Akram, 2022).

An example to illustrate the Keynesian transmission mechanism is as follows. Suppose the repo rate is increased by the central bank. This discourages the lending and money creation capacity of banks (Fikri, 2018). The money supply contracts and causes excess demand in the money market. Sales of money market instruments cause downward pressure on their prices, and upward pressure on interest rates. The higher interest rates discourage investment and result in a decrease in aggregate expenditure (Del Negro et al., 2015). If production decreases, real GDP and thus real income decreases, and the level of economic activity declines. Monetary changes are transmitted to the real sector via the interest-investment link. Real sector changes affect aggregate income as

well as the price level. These steps illustrate the link between the monetary sector and the real sector through the transmission mechanism.

The Keynesian framework can be used to explain different observed patterns in the macroeconomy. The monetary policy is very important for stabilizing the economy using various channels of the transmission mechanism such as asset prices, interest rates, monetary targets, and exchange rates, among others (Akram, 2022). The argument is that monetary policy can quickly cure the ills facing the economy and is increasingly becoming popular relative to fiscal policy (Ncanywa & Ralarala, 2022). The Keynesian framework in this paper map the route from changes in asset prices (housing prices in this case) to changes in interest rate, as to see the role played by house prices on monetary policy. Most studies found that house prices could contemporaneously convey important information for the conduct of monetary policy (Damen, Vastmans & Buyst, 2016; Bernanke et al., 2018; Rosenberg, 2019; Martin, Schmitt & Westerhoff, 2022; Olusegun, 2022).

Dalziel (2002) explained three essential features of the modern monetary policy, of which only the first can be at all consistent with classical monetarism. This first feature is that the primary objective of monetary policy is to maintain a low rate of inflation. In many countries including South Africa, the target rate of inflation is preannounced by the government or the central bank, typically with agreement by both institutions. The second feature is that the instrument of monetary policy is not the quantity of money but the base interest rate at which the financial sector borrows cash reserves from the central bank. If a central bank judges that on current policy settings, domestic inflation is likely to rise above target, and the bank raises its base interest rate (Bernanke et al., 2018). If the economy is weak and there are no anticipated inflationary pressures, the bank lowers the base interest rate (Kim & Mehrotra, 2022). Third, given that monetary policy is credible, and expectations stabilised around the target inflation rate, the main transmission mechanism from instrument to objective is understood to be through changes in the "output gap" between aggregate supply and aggregate demand (Dalziel, 2002). Supply-side capacity, or potential real gross domestic product (GDP), is assumed to grow at a relatively steady rate depending on real factors such as population growth, investment in physical and human capital, and the rate of technological advance (Olusegun, 2022; Wang, Wang & Guo, 2022). If aggregate demand grows faster than capacity, this generates inflationary pressures. If demand grows too slowly, there is unnecessary unemployment and a risk of recession. By adjusting its base interest rate the central bank can influence the growth rate of aggregate demand, and so meet its inflation target.

2.2 Empirical literature

Following the literature debates on the asset price channel, some studies alluded to the importance of considering the changes that can be done by house prices in the South African economy and related countries, particularly on monetary and macro-prudential policies (Taguchi, Sahoo & Nataraj, 2015; Gumata & Ndou, 2017; Ducastel & Anseeuw, 2017; Ndou, Gumata & Ncube, 2018). For instance, Gumata & Ndou (2017) indicated the importance of South Africa in adopting a floating exchange rate and its influence on the behavior of domestic monetary variables. It further alludes to Gilbert et al (2017) that announcement of changes in asset prices in open economies results in large capital flows that affect the domestic behavior of monetary policy variables in the transmission mechanism.

Though most studies that looked at the asset price channel the focus was not on house prices (Taguchi et al, 2015; Ducastel & Anseeuw, 2017), and also those studies that looked at asset prices were linking it with some macro-economic variables other than interest rates (Berger et al, 2018; Tita & Opperman, 2021; Dlamini, & Ngalawa, 2022). Taguchi et al, (2015) examined the impact of capital flows on asset prices and alluded to the importance of an exchange regime to asset prices. Ducastel and Anseeuw (2017) point to an asset price channel on farming land as an important investment that can hugely contribute to the financial sector by capitalizing on the South African agricultural sector. Berger et al (2018) link the effects of house prices with consumer spending behavior, while Tita & Opperman (2021) link house prices to household income and wealth creation. Dlamini & Ngalawa (2022) employed a dynamic stochastic general equilibrium methodology to establish the small effects of monetary policy on house prices. Twinoburyo & Odhiambo (2018) viewed international literature that includes South Africa on the relationship between monetary policy and economic growth. There was a weak association in developing countries, especially those with underdeveloped financial markets.

However, the study of Bernanke et al. (2018) informed a route of the asset price channel through the role of house prices on the monetary policy transmission mechanism.

Some empirical studies in developing and developed countries have contributed to the debate on the channels of monetary policy. There are some studies on the transmission mechanisms of monetary policy beyond the standard interest rate channel focusing on how monetary policy affects the economy through other asset prices (Rey, 2016; Eichenbaum, Rebelo & Wong, 2022). When house prices were considered, it was confirmed that direct effects on housing expenditures, household wealth, and bank balance sheets could affect aggregate demand. For instance, a study by Claessens & Kose (2017) established that house prices are less volatile than equity prices, and they have permanent effects on wealth and consumer spending though they do that at a lag. So, the house process effect has a weak relation to interest rate changes as they are traded in less liquid markets. Further alluded by Bernanke et al. (2018) that the knowledge of the housing market can play a role in the monetary transmission mechanism. It was discovered that on the household expenditure effects, the expansionary monetary policy could increase aggregate demand. Interest rates are lowered, leading to a low cost of financing housing and an increase in the house price. Firms find it profitable to build housing, housing expenditure will rise, and so aggregate demand will rise (Dorling, 2021). Housing prices are an essential component of household wealth, which affects consumer spending. It is argued that the housing market is of central concern to monetary policymakers (Rosenberg, 2019; Cumming & Hubert, 2022; Dlamini & Ngalawa, 2022).

3 METHODOLOGY

3.1 Model specification

The paper aims to examine the role of house prices in the monetary policy transmission mechanism in South Africa using an econometric methodology called the Vector Error Correction Model (VECM). The VECM comprises the three-month domestic interest rate, the log of real house prices, the changes in the domestic consumer price index, and the log of real Gross Domestic Product. Following Fikri (2018), Bernanke et al (2018), Dong et al. (2021), Cumming & Hubert (2022), and other reviewed authors in the literature review section, the choice of variables in the VECM reflect the theoretical setup of a Keynesian model and the classical monetarism as follows:

$$IR = \beta_0 + \beta_1 HP + \beta_2 CPI + \beta_3 GDP + \epsilon_t \dots\dots\dots (1)$$

Where IR represents interest rates, HP real house prices, CPI consumer price index for inflation, GDP gross domestic product for economic growth, β_0 constant, β_{1-3} slope coefficients, and ϵ_t error term.

3.2 Data

The model is estimated for South Africa using quarterly data from 1990 to 2020. The sample is large enough to cover problems that can be created in the estimation process (Asteriou, Dimitras & Lendewig, 2013). The data is sourced from the South African Reserve Bank (SARB). In this study, full simultaneity between monetary policy and house prices is assumed (Bjørnland et al., 2008).

3.3 Estimation techniques

The vector error correction model (VECM) methodology begins with the Johansen cointegration technique (Asteriou et al, 2013). This methodology uses the error-correction model that determines the speed of adjustment to equilibrium, which will include both long-run and short-run information. The first task is to make sure the data is integrated in the same order (Raimbekov, Sładkowski, Syzdykbayeva, Azatbek & Sharipbekova, 2022). This is done by using unit root tests to examine the stationarity of data sets. Thus, the variables are subjected to the Augmented Dickey-Fuller (ADF) test and the Phillips-Perron (PP) test. The tests are also done to avoid the spurious regression problem, which exists if unit roots are present. If the unit root is present, we work with differenced data. The PP statistics is a modification of the ADF t-statistics that consider the less restrictive nature of the error process (Asteriou et al., 2013).

Variables are cointegrated if they are related and move together so that the stochastic trends would be like each other and when they are combined, it should be possible to find a combination of them that eliminates the non-stationarity (Song et al., 2021; Raimbekov et al., 2022). In theory, this should only happen when there is a real relationship linking the variables together. Therefore, cointegration is used as a way of detecting the presence of economic structures. In cointegration, the long-run relationship between variables indicates a common trend that links them together. For a long-run equilibrium relationship to exist there should be a linear combination of stationary variables (Asteriou et al., 2013).

Johansen followed five steps to conduct the VECM (Brooks, 2019). Firstly, the order of integration of the variables (unit root test) is tested to test stationary variables. The desired case is when all variables are integrated in the same order and then proceed with the cointegration test. However, it is important to stress that it is not the case, and even in cases where a mix of I (0), I (1), and I (2) that variables are present in the model, the cointegration relationship might exist. The inclusion of such variables will affect the results and therefore more consideration should be applied in such cases (Asteriou et al., 2013; Brooks, 2019). The second step involves setting the appropriate lag length of the model. Finding the optimal lag length is important to obtain Gaussian error terms. In the third step, we choose the appropriate model regarding the deterministic components in the multivariate system. In this step, the decision of whether to include an intercept or a trend in the short run or the long run or both models is taken. Fourthly, the rank of the matrix or the number of cointegrating vectors is determined. Lastly, there is an estimation of the impulse response

functions of economic growth and inflation to shocks in interest rate, house prices, and other variables. The impulse response analysis allows for a convenient representation of the time path of effects. In addition, a variance decomposition is included to uncover the short-run relationships among variables (Song et al., 2021). The results in the estimations are subjected to diagnostic checks that test the stochastic properties of the model, such as residual autocorrelation, heteroscedasticity, and normality, among others.

The estimation of the error correction model allows testing for Granger causality (Wang et al., 2022). The framework allows for a causal link between two variables stemming from a common trend or long-run equilibrium relationship. This framework considers the possibility that the long-run information in the data represented by a lagged level of a variable, X may help to explain the current changes in another variable, Y, even if the short-run information in the data given by the past changes does doest (Asteriou, 2013).

4. EMPIRICAL RESULTS AND DISCUSSION

4.1 Unit root test results

If a series becomes stationary after d numbers of difference, then it is said to be integrated of order d (Brooks, 2019). Two asymptotically equivalent tests have been performed: the ADF and the PP test. The results of the unit root tests for all the variables in the estimated model discussed in section 3.1 above for the period 1990 to 2020 are presented in table 1.

Table 1: The results of various unit root tests

| Type | Order | CPI | GDP | HP | IR |
|------|------------------|-----------|-----------|----------|-----------|
| ADF | Level | -2.609 | -3.67 | -2.13 | -3.48 |
| ADF | First difference | -12.25*** | -7.28*** | -7.63*** | -6.12*** |
| PP | Level | -1.06 | -4.53 | -2.08 | -2.838 |
| PP | First difference | -16.96*** | -24.45*** | -9.08*** | -6.139*** |

Notes: CPI-Consumer Price Index; GDP-Gross Domestic Product; HP- house prices; IR-Interest rates; ADF-Augmented Dickey-Fuller; PP- Phillips-Perron; *** indicates significance at 1%.

The results of the ADF test show that the series of house prices, growth, CPI, and interest rates are non-stationary when variables are defined in levels (see table 1). First differencing the series removes the non-stationary components and the null hypothesis of non-stationarity is rejected at the 1% significant level suggesting that these variables are integrated of order one. The results of the PP test are not fundamentally different from the respective ADF test results. The lag truncation for the Bartlett kernel was chosen according to the Newey and West suggestions (Asteriou, 2013). The results after first differencing the series reject the null hypothesis of the presence of a unit root, suggesting that the series are integrated of order one. The results confirmed that differencing once was all that is required to bring these variables to stationarity. Hence the cointegration tests were conducted.

4.2 Cointegration analysis

Once the stationarity order has been established, a cointegration test should follow. The test used for cointegration is the one proposed by Brooks (2019). This became necessary to find variables that exhibit long-run equilibrium. Firstly, we started with the choice of optimal lag length. This is important to avoid spurious rejection or acceptance of estimated results. If the lag length is too

large, the VECM is more likely to pick up within sample random variation as well as any systematic relationship, because there is the need to estimate a great number of parameters (Song et al., 2021). The lag length also influences the power of rejecting the hypothesis. For instance, if k is too large, the degree of freedom may be wasted. Moreover, if the lag length is too small, important lag dependences may be omitted from the VECM, and if the serial correlation is present the estimated coefficients will be inconsistent (Asteriou, 2013).

The optimal lag length is suggested by Akaike Information Criteria (AIC), Schwarz Information Criterion (SIC), Hannan-Quinn criterion (HQ) Final Prediction Error (FPE) as well as Likelihood Ratio (LR) test. This is because all these criteria can produce conflicting lag length choices. However, the decision about the lag structure of a VAR model could be because a given criterion produces a white noise residual and conserves degrees of freedom (Song et al, 2021). In this study, table 2 presents the selection of an optimal lag length.

Table 2: VAR lag order number selection criteria

| Lag | Log-Linear | LR | FPE | AIC | SC | HQ |
|-----|------------|-----------|-----------|-----------|-----------|-----------|
| 0 | -945.4854 | NA | 708.6154 | 17.91482 | 18.01533 | 17.95556 |
| 1 | -716.7719 | 435.8502 | 12.80876 | 13.90136 | 14.40389* | 14.10504 |

Notes: * indicates lag order selected by the criterion; LR: Likelihood ratio; FPE: Final prediction error; AIC: Akaike information criterion; SC: Schwarz information criterion; HQ: Hannan-Quinn information criterion.

Table 2 indicates that the optimal lag length is 5 as indicated by most criteria (as indicated by*), which are more reliable. The paper employed the Johansen multivariate cointegration techniques. The cointegration technique was chosen because it performs better than single-equation and alternative multivariate methods. The results of the cointegration tests are reported in table 3.

Table 3: A cointegration analysis

| H_0 : $rank = p$ | Maximum Eigenvalue Statistics | Trace Statistics | Eigenvalue |
|-----------------------|-------------------------------|------------------|------------|
| $\rho = 0$ | 44,12* | 27,58 | 86,20* |
| $\rho \leq 1$ | 28,21* | 21,13 | 42,09* |
| $\rho \leq 2$ | 13,20 | 14,26 | 13,86 |
| $\rho \leq 3$ | 0,667 | 3,841 | 0,667 |

Notes: *represent* hypothesized number of cointegrating equation(s)

Trace and maximum eigenvalue statistics presented in table 3 indicate that there are two cointegrating relations in the system. The cointegrated variables must have an error correction representation in which an error correction term must be incorporated into the model. Accordingly, a vector error correction model is formulated to reintroduce the information lost in the differencing process, thereby allowing for long-run equilibrium as well as short-run dynamics (Asteriou et al, 2013). Based on the given explanation, we then move on to the next stage of generating an error correction model. These results are in line with Keynesian theory in that the monetary policy

variables are related to real sector variables as the cointegration relationship implies a long-run relationship (Del Negro et al., 2015; Fikri, 2018; Rosenberg, 2019).

4.3 Vector error correction modeling (VECM)

Given that variables are cointegrated, one can proceed to estimate the VECM. The model contains information on the long-run, and short-run relationship between variables and speed of adjustment (error correction model). To check for the long-term relationship between the dependent and independent variables, the variables are subjected to estimation using the specification stated in section 3.1. To specify the VECM, the number of cointegrating relationships obtained in the previous step, the number of lags, and the deterministic trend assumption in the cointegration test are all used. The fact that variables are cointegrated informed the use of the VECM (Raimbekov et al., 2022). The model allows the long-run behavior of endogenous variables to converge to their cointegrating (that is long-run equilibrium) relationships while allowing a wide range of short-run dynamics (Brooks, 2019).

The long-run effects of house prices on interest rates are obtained from the normalized cointegrating equations. House prices and inflation have a negative and significant relationship with interest rates. The statistical significance of the variables was established at a five percent significance level. These results are in line with most studies found in the literature (Rosenberg, 2019; Cumming & Hubert, 2022). A normalized cointegration equation is as follows:

$$IR = -57.79 - 5.8 \times 10^{-7} HP - 0,3569 CPI - 0.735 GDP \dots\dots\dots (2)$$

The result revealed that a 1 percent increase in house prices could cause over a 0,00058 percent proportional decrease in interest rates and an increase in inflation could cause over a 0,357 percent proportional decrease in interest rates. These results indicate a significant possibility of the house price channel on monetary policy though 0.00058 percent is a small number indicating a weak link. These results are in line with the studies of Bernanke et al (2018) who suggested the house price channel as a possible link to the monetary transmission mechanism. In addition, a study by Claessens & Kose (2017) confirmed a permanent link between house prices and interest rates, though this happens after a lag. The strength of this model is supported by scholars who identified that the role played by house prices on monetary policy occurs in an inflation-controlled framework as the case in South Africa (Apergis et al, 2015; Twinoburyo & Odhiambo, 2018; Dlamini & Ngalawa, 2022).

For economic growth, a 1 percent increase in it would lead to over 0,735 percent proportional decrease in interest rates. The results imply that the general price levels must be set to a given target to achieve the projected future growth of the economy (Raimbekov et al., 2022). Thus, a moderate annual inflation growth rate would be required to stimulate the economy to attain long-term growth. As an instrument of monetary policy, interest rates should be used with caution in order not to retard the development process of the economy. For instance, mopping up excess money in the economy must be carefully carried out in a way it will not generate higher lending interest rates as well as lower savings ratios (Twinoburyo & Odhiambo, 2018). Investment, through house prices, though important for long-run growth, must be properly channeled to the sectors of the economy that are growth enhancing (Dong et al., 2021; Olusegun, 2022).

The error correction model estimate of -0,1089, also called speed of adjustment shows that interest rate, house prices, inflation, and GDP adjust to the deviations from their long-run paths. This long-run relationship is significant at 1 percent. However, this indicates that the adjustment process takes a very long period with a speed of around 11 percent. To these results, the short-run effects of monetary policy on real activity deviate from the long-run effect. The implication is that the short-run impact of monetary policy may be very low, although significant. Besides, the results indicate that the longer-run policy actions and measures on house prices can bring desirable and required adjustments to the economy at large (Dorling, 2021). The monetary authorities should, for the immediate period, focus on the use of interest rates as policy instruments to actualize its objectives. Hence, targeting house prices can be a long-run policy goal, and the model is found stable as shown in the polynomial AR root that all dots are inside the circle (figure 1).

Inverse Roots of AR Characteristic Polynomial

Figure 1: Inverse roots of AR characteristic polynomial

4.4 Impulse Response Functions

The impulse response functions trace the temporal and directional response of endogenous variables to a change in one of the structural innovations (Brooks, 2019). Impulse response functions indicate the lag structure in the economy. It shows the responses of a particular variable to a one-time shock in each of the variables in the system. The interpretation of the impulse response functions should take into consideration the use of the first differencing of the variables as well as the vector error correction estimates. Figure 2 illustrates the combined impulse response functions for the interest rate- house price series.

Figure 2: Impulse response functions

Notes: LHP- house prices; IR- Interest rates; CPI- Consumer Price Index; LGDP- gross domestic product

A one-time shock to the first difference in a variable is a permanent shock to the level of that variable (Ncanywa & Ralarala, 2022). This allows issues to be addressed concerning the effects of monetary policy on the real economy. Of particular interest in this study are the dynamic responses of interest rates to innovations in each variable (figure 2). The ordering of the variables used for the study followed from interest rates to house prices, GDP, and inflation. A shock to interest rates generates a negative response to other variables beginning from the second quarter.

4.5 Variance Decomposition

Variance decompositions indicate the proportion of the movements in a sequence due to its shocks versus shocks to the other variables. It shows the fraction of the forecast error variance for each variable that is attributable to its innovations and innovations in the other variables in the system (Asteriou, 2013). The variables are listed according to the increasing order of responsiveness, with the least responsive variables coming first. Based on the assumptions of sluggish adjustments of the goods market, economic growth and inflation were listed first. Following were house prices and then lastly, interest rates, on the assumption of quick responses of the monetary variables to shocks in interest rates. The variance decomposition is presented in Table 4 using the Cholesky decomposition method, to identify the most effective instrument to use in targeting each variable of interest. This helps in separating innovations of the endogenous variables into portions that can be attributed to their innovations and innovations from other variables.

Table 4: The results of the forecast error variance decomposition

| Variable | Standard error | Period (Month) | HP | CPI | IR | GDP |
|----------|----------------|----------------|---------------|---------------|----------------|-------|
| HP | 4.171 | 1 | 99.847 | 0.000 | 0.152 | 0.000 |
| | 5.706 | 4 | 82.469 | 0.627 | 11.472 | 5.430 |
| | 6.121 | 7 | 72.108 | 1.799 | 18.992 | 7.090 |
| | 6.283 | 10 | 69.797 | 2.613 | 20.457 | 7.132 |
| CPI | 1.104 | 1 | 0.911 | 99.085 | 0.003 | 0.000 |
| | 2.058 | 4 | 2.027 | 93.612 | 0.214 | 4.146 |
| | 2.291 | 7 | 4.277 | 90.867 | 0.718 | 4.137 |
| | 2.331 | 10 | 5.179 | 89.121 | 1.400 | 4.297 |
| IR | 0.650 | 1 | 0.000 | 0.000 | 100.000 | 0.000 |
| | 0.767 | 4 | 0.304 | 2.198 | 92.656 | 4.041 |
| | 0.816 | 7 | 2.792 | 4.555 | 88.446 | 4.206 |
| | 0.850 | 10 | 6.026 | 6.026 | 84.072 | 3.770 |

| Variable | Standard error | Period (Month) | HP | CPI | IR | GDP |
|----------|----------------|----------------|----------|--------|--------|---------------|
| GDP | 0.988 | 1 | 7.02E-05 | 2.623 | 0.158 | 97.217 |
| | 2.771 | 4 | 0.226 | 11.530 | 6.264 | 81.979 |
| | 3.431 | 7 | 0.198 | 14.960 | 17.166 | 67.675 |
| | 3.636 | 10 | 0.454 | 16.398 | 20.598 | 62.549 |

Notes: CPI-Consumer Price Index; GDP-Gross Domestic Product; HP- house prices; IR-Interest rates

As anticipated, own shocks constitute the predominant sources of variations for all the variables in the model. From Table 4, the predominant source of variation in house price forecast errors is own shocks, which account for between 69,3 percent and 99,8 percent of the forecast errors in house prices. Innovations from interest rates are a relatively important source of forecast error variance in monetary activity. In the first quarter inflation and economic growth account for zero percent and interest rates accounts for 15 percent. Both inflation and economic growth are less significant.

4.6 Granger Causality test results using ECM framework

The estimation of the error correction model allows testing for Granger causality. The framework allows for a causal link between two variables stemming from a common trend or long-run equilibrium relationship (Wang et al., 2022). This framework considers the possibility that the long-run information in the data represented by a lagged level of a variable, an independent variable, may help to explain the current changes in another variable, the dependent variable, even if the short-run information in the data given by the past changes do not (Asteriou et al, 2013). A VAR Granger-causality test was presented in Table 5.

Table 5: VAR Granger Causality/Block Exogeneity

| Dependent variable: Interest rates | | | | |
|------------------------------------|-------------|----|-------------|--|
| Excluded | Chi-squared | df | Probability | |
| HP | 6.533355 | 2 | 0.0381 | |
| CPI | 5.090648 | 2 | 0.0784 | |
| GDP | 11.31267 | 2 | 0.0035 | |
| All | 19.18603 | 6 | 0.0039 | |
| Dependent variable: HP | | | | |
| Excluded | Chi-squared | df | Prob. | |
| IR | 11.10653 | 2 | 0.0039 | |
| CPI | 1.055781 | 2 | 0.5898 | |
| GDP | 3.068139 | 2 | 0.2157 | |
| All | 13.44634 | 6 | 0.0365 | |
| Dependent variable: CPI | | | | |
| Excluded | Chi-squared | df | Prob. | |
| IR | 0.522466 | 2 | 0.7701 | |

| Dependent variable: GDP | | | | |
| Excluded | Chi-squared | df | Prob. | |
| IR | 14.47412 | 2 | 0.0007 | |
| HP | 0.671648 | 2 | 0.7147 | |
| CPI | 8.966218 | 2 | 0.0113 | |
| All | 27.10054 | 6 | 0.0001 | |

Notes: CPI-Consumer Price Index; GDP-Gross Domestic Product; HP- house prices; IR-Interest rates; df- degrees of freedom

Table 5 shows a bi-directional causality in the interest rate–house prices and interest rate-economic growth series. There is unidirectional causality from inflation to interest rates and economic growth. The findings of this sub-section imply that house prices can be a possible link in the monetary transmission process as alluded to in the literature (Rosenberg, 2019; Dong et al., 2021; Wang et al., 2022).

5. CONCLUSIONS AND RECOMMENDATIONS

The paper aimed to examine the role of asset prices in the monetary policy transmission mechanism in South Africa. The paper employed the vector error correction model and Granger causality tests that incorporated quarterly data from 1990 to 2020. The series comprised the domestic interest rate, consumer price index, GDP (real GDP at constant prices), and real house prices. Based on the order of the significance of the tests, the detection of causality between these variables arises, which indicates that house prices play a significant role although it is weak and the ‘other asset price channel’ is the possible channel of monetary transmission. There was bi-directional Granger causality between house prices and interest rates.

The results further indicated that the role of house prices on interest rates should take place in an inflation-controlled framework. Inflation targeting of the monetary policy of South Africa, transparency, and accountability have improved immensely, and further improvements are in prospect. The weak link indicates that monetary authorities are unlikely to have informational advantages when looking at house prices. Meaning, that changes in house prices should affect monetary policy only to the extent that they affect the South African bank’s forecast for inflation and the outlook on economic growth. It is recommended that the asset price channel can be followed with inflationary precautions to evaluate the stance of the monetary policy, especially the role shown by house prices.

ABSTRACT

Food insecurity in cities is exacerbated by urbanisation and population growth. According to the City of Johannesburg Review (City of Johannesburg Review 2020/21:12), the City of Johannesburg's population has increased by approximately 12% in the last two years, from 5,05 million to 5,74 million. Urban farming has emerged as the best solution for food security and job creation. Urban farming can be practised in any available space suitable for growing agricultural produce for food sustainability and income, such as backyards and rooftops. However, produce loss can occur both after harvest and during transportation, and for many smallholder farmers, post-harvest processing technologies and efficient transportation networks may be prohibitively expensive. The purpose is to gain a detailed understanding of the transportation options currently used by smallholder urban farmers and which other transportation options could be used to improve the delivery of produce to current and potential customers in and around Johannesburg. For the purpose of this study, quantitative data were collected on the transportation options available to urban farmers and their customers in Gauteng province. The smallholder urban farmers were given either a digital or a physical questionnaire. The questionnaires were distributed via WhatsApp and other digital modes available to the urban farmers. The sampling frame were 80 smallholder urban farmers identified in the Johannesburg area and surrounds. According to the data collected, urban farmers are aware of the different transportation options available to them; however, they do not utilise outsourced transportation alternatives. Outsourcing transportation will help the smallholder urban farmers to reduce damage to or loss of produce caused by unsuitable vehicles to deliver fresh produce. In addition, outsourcing transportation will reduce delivery time, which will result in preserved freshness of the produce as less time will be spent in transit.

Keywords: Transportation, outsourcing, urban farming, smallholders, urban agriculture

1. INTRODUCTION

Urbanisation is a key factor that leads to overpopulation in metropolitan areas, which in turn results in food insecurity. Urbanisation is defined as movement of people from rural areas to cities for

better living conditions (Szabo, 2015:28) and occurs when people are looking for better opportunities, such as employment, education, and health facilities. According to the City of Johannesburg Review (2020/21:12), the population of the City of Johannesburg has increased by approximately 12% in the past two years, from 5,05 million to 5,74 million. Approximately 30% of the population are born in other provinces (Crosthwaite, 2017:1). Urbanisation has led to food poverty and insecurity as the unemployment rate increased from 29,1% to 32,5% (Statistics South Africa, 2021:3).

Food poverty occurs when a household or an individual cannot access healthy and nutritious food, due to the lack of affordability (Crosthwaite, 2017:1). On the other hand, food insecurity is the lack of access to enough nutritious and affordable food (Fawole, Ilbasimis & Ozkan, 2015:1). Hence, urban farming has become an optimal solution for food security and generation of income in urban areas. Urban farming is described as an individual or a group of people who utilises the available space in their communities, backyards, and rooftops for planting fresh agricultural produce for food sustainability and income (Steele, 2017:1). These urban farmers plant for personal consumption, to sell in neighbouring areas, and to donate produce to schools and churches for those in need (Gwamba, 2018:13). According to Molelu (2015:17), over the years, urban farming networks have been successful in terms of food security and job creation. However, due to a lack of resources and knowledge, farmers have faced difficulties in transporting their produce effectively and efficiently (Ngcoya & Kumarakulasingam, 2017:48).

Transportation is critical in enabling people and organisations to interact and trade information, goods, and services (Miller, 2018:552). Urbanisation has increased in demand for an effective and efficient transportation network in urban areas (Turok, 2017:101). This emphasises the importance of an effective transportation network for facilitating the delivery of product to customers and assuring timely delivery of produce (Speranza, 2018:835). Most food spoilage occurs during transportation from the urban farms to customers (Hlommendlini, 2019:1). Food security and sustainability awareness have grown in popularity over the years. This is evidenced by the significant number of people in urban areas who have begun farming on available land (Hammond, Brown, Burger, Flanagan, Fristoe, Mercado-Silva, Nekola & Okie, 2015: 758). However, the issue of food spoilage as a result of insufficient storage and transportation facilities receives less attention.

Numerous smallholder farmers face difficulties with post-harvest handling practices and effective transportation networks, which can be prohibitively expensive. According to Sawicka (2019:7), an estimated 40% to 50% of the fresh produce loss occurs post-harvest and during transportation. Additionally, a lack of awareness about market information and transportation networks has contributed to South Africa's food waste (Hlommendlini, 2019:2). The smallholder urban farmers are greatly affected by food spoilage as they do not have sufficient knowledge of transportation networks due to lack of exposure (Lutz, Smetschka & Grima, 2017:925). Additionally, due to their lack of exposure to these networks prior to starting their urban farms, their only knowledge of deliveries is to make use of their own vehicles or alternative vehicles that are available for them to use freely (Lutz et al., 2017:925).

This resulted in many farmers opting to use their private vehicles to transport produce to the customers and, in some instances, the customer collects their order from the farmers (Robinson, 2018:2). However, smallholder urban farmers recognised that delivering product to customers via

private vehicles is expensive and time consuming (Robinson, 2018:2). At the same time, the farmers who do not own private vehicles may walk, use bicycles or even collectively hire a vehicle to make deliveries (Grocycle, 2021:1). The farmers who use their private vehicles for deliveries began to research the benefits and consequences of outsourcing a transportation company to do deliveries (Robinson, 2018:2). Moreover, the farmers prioritise the cost-efficiency, reliability, and suitable transportation network to get the produce from the farm to the customer in a timely manner.

The lack of knowledge about market information and the transportation network has led to smallholder urban farmers within Gauteng being incompetent. The lack of transportation methods and strategies for maximising their effectiveness and reaping the benefits necessary to build the business resulted in customer dissatisfaction and loss of produce in transit. The literature review focuses on identifying and evaluating the transportation networks currently available to urban farmers as well as finding ways to improve or design a new transportation network to increase reliability and customer service while reducing produce spoilage and costs. Through investigating the above, the literature review below is laid out under the following headings: Self-sufficient urban farmers, commercial customers and then insourcing versus outsourcing transportation to deliver the produce to the consumers.

2. LITERATURE REVIEW

2.1 URBAN FARMERS

The urban farmer is described as a person in an urban area who makes use of communities, backyards, even rooftops for the production of agricultural products for food sustainability and revenue generation (Steele, 2017:1). More examples of urban farming are balcony gardening, growing in vacant lots, rights-of-way, fruit trees, market farms, and raising livestock (Steele, 2017:4). However, land availability for farming in the cities has been a constraint due to industrialisation and urbanisation (Kyaw & Keong, 2017:342). Many farmers have encountered this land availability constraint and, as a result, have adopted vertical and pot plant farming strategies in order to produce adequately (Chatterjee, Debnath & Pal, 2020:159). During the recent lockdown, many people in urban areas, such as Bedfordview, started farming projects, which increased the number of farmers in the area to 120 (Abrahams, 2020:2). Consequently, urban farming supplies 20% to 60% of food, such as vegetables, and medicinal and aromatic plants in most households (Myeni, Thayhana, Randela & Mokoena, 2019:2). Urban farmers start with a sustainable garden of produce to feed their families and most move into the direction of growing enough to sell and start a sustainable business (Diehl, Oviatt, Chandra & Kaur, 2019:1378).

2.2 Customers

Since there are various distribution channels, smallholder urban farmers must determine how they will distribute and sell their produce to their customers. These distribution channels are classified into two types: both formal and informal (Siegener, Sowerwine & Acey, 2018:12). A few examples of formal distribution channels would be when farmers sell their produce to institutions or directly to retailers and farmers' markets (Siegener et al., 2018:12). On the other hand, smallholder urban farmers can also make use of an informal distribution channel, which consists of crop swaps, mobile food markets and online marketing channels (Siegener et al., 2018:13). The choice of

distribution channel type necessitates the development of a transport network that will allow for the movement of their produce (Speranza, 2018:835). Depending on the distribution channel or channels selected by the smallholder urban farmers, this may affect the transport methods used, namely insourcing or outsourcing transportation (Siegener et al., 2018:14).

2.3 Insourcing transportation

When smallholder urban farmers use their own vehicles to deliver produce, they incur a variety of costs and potential problems, such as a lack of suitable vehicles to preserve the freshness of produce while in transit or a lack of a reliable vehicle to transport produce to customers on a regular basis (Negi & Trivedi, 2021:3). Therefore, it is difficult for farmers to manage their urban farms, package produce as well as deliver produce to customers. Owing to the nature of these activities, they experience a limited window of time (Kader, 2004:296). Customers have higher service expectations in terms of produce being delivered on time and the quality of the produce (Kader, 2004:296).

Thus, while dealing with a start-up urban farm, it is critical to analyse the costs of insourcing versus outsourcing transportation. (Snyman, 2018:4). Owing to financial constraints, most South Africans keep their vehicles for a longer period of time (Staff Writer, 2020:2). Owning a car has fixed and variable costs to be considered (Snyman, 2018:4). Driving efficiently and renewing your licence on time save on variable costs (Snyman, 2018:4). All the above costs pale in comparison to the amount of money one must spend on fuel per year (Snyman, 2018:4). Using outsourced transportation eliminates additional costs, such as insurance and maintenance, as there will be a fixed cost from A to B (Snyman, 2018:4).

Coordinating growing and delivering produce to customers simultaneously may be difficult for urban farmers, and the reliability of transportation has an impact on the farmer's reputation (Vencataya, Pudaruth, Dirpal & Narain, 2018:230). Numerous urban farmers who operate their own trucks have struggled to sell high-quality fruit owing to spoilage and transportation concerns, which is why they consider outsourcing (Moosa, 2019:2).

2.4 Outsourcing transportation

Outsourced transportation bridges the gap for farmers by providing the know-how for an appropriate mode of transport (Banister, 2001). Outsourcing transportation can be defined as a business or an individual contracting with a third-party logistics provider or transport provider to transport specific products because they are unable or unwilling to transport the products themselves or would rather focus on their core business activities (The Supply Chain Consulting Group, 2021:1).

Outsourcing transportation would provide many benefits to urban farmers, including cost savings from using a third-party logistics provider, who is often able to provide the service at a reasonable price (The Supply Chain Consulting Group, 2021:2). An external transport company provides the expertise to deliver goods to customers, thus allowing smallholder urban farmers to focus on their core business activity, namely farming and providing high quality produce to their customers as well as minimising their wastage of produce (GTZ, 2018:1)

Uber launched in South Africa in 2013 as a service that transports people to their desired location (Mayuri Pillay, 2016:1). In 2016, the company launched a fast-food delivery service called 'Uber

Eats’, followed by an additional feature service in the Uber app called ‘Uber Connect’ in 2020 (Mercury Reporter, 2019:1; Staff Writer, 2020:2). Uber Connect is a feature on the Uber application that allows individuals or businesses to use their smartphones and request a parcel collection and delivery to a destination (Staff Writer, 2020:3). Individuals and businesses alike gain from this program because it enables them to utilise their smartphones to expeditiously deliver goods to their customers’ specified locations. Additionally, the usage of the Uber application enables urban farmers and customers to track and trace their product packages in real time (Staff Writer, 2020:4), resulting in greater customer satisfaction and, ultimately, customer loyalty (GTZ, 2018:2).

Another example of a third-party logistics provider is a company called ‘E-cargo bike’, which launched in South Africa in 2018 (Staff Writer, 2018:4). An electronic bike is used for the transport and delivery of goods aimed at providing a cost-effective, safer, and greener ‘last-mile’ solution in the freight distribution system (Staff Writer, 2018:4). Uber, E-cargo bike, and other third-party logistics providers are possible options for farmers to combat the issues that arise from making use of their own vehicles to transport produce to customers (GEP, 2019:1).

3. RESEARCH METHODOLOGY AND DESIGN

The most appropriate research design for this study was descriptive and evaluative. According to Saunders, Lewis and Thornhill (2019: 186-188), a descriptive design is a study that asks participants a variety of questions about the topic of interest in order to acquire insight. Additionally, evaluative research is defined as a study that determines the topic’s effectiveness (Saunders et al., 2019:188). The demographic data acquired by the questionnaire were descriptive in nature, as the mean, mode, and standard deviation were utilised to analyse the data. The questions asked in the questionnaire were descriptive in nature, to identify the transportation alternatives available to urban farmers and their customers in Johannesburg.

This study analysed the current modes of transportation utilised by smallholder urban farmers and identified alternative means of transportation that would efficiently and effectively transport their produce to their customers, hence Pragmatism was the best ideology to use. The data were collected using a structured questionnaire, which was distributed electronically and physically to farmers within Johannesburg. The data collected by this questionnaire provided the relevant information to address the research question, thus identifying transportation options available to the urban farmers and their customers within Johannesburg.

The data were descriptive in nature, assisting in the identification of the urban farmer profile, type of urban farm, and transportation options available to urban farmers and their customers. Some questions were either similar or related to previous questions asked with the intent to confirm the information provided in previous questions as accurate, relevant, and reliable. The information gathered by the demographic questions in the questionnaire can be generalised and a general conclusion can be assumed.

Primary data were collected by means of a quantitative survey using a structured questionnaire. The quantitative method was more suitable as the research requires information in the form of variables from a group of urban farmers. It also allows for more data to be collected over a shorter period of time (Mander, 2017). This research has a limited time frame; hence, it was critical to conduct research on a reliable group of farmers in Johannesburg. Furthermore, a quantitative

method allows for more variables to be collected and analysed, which will allow for a bigger picture of the problem.

The Gauteng smallholder urban farmers served as the unit of analysis for this research. The sampling frame was 80 from the 120 urban farmers identified by Abrahams in 2020 in the Johannesburg area and surrounds. The survey was administered to 80 urban farmers in the province. The urban farmers received either a digital questionnaire or a physical questionnaire.

To conduct the surveys in compliance with COVID-19 requirements, researchers joined WhatsApp groups for urban farmers. The questionnaires were made available to urban farmers via WhatsApp and other digital platforms. Social media facilitated contact between researchers and participants, allowing members of each group to complete the questionnaire and participate in the study. When possible, questionnaires were delivered and collected in person.

4. RESULTS AND DISCUSSION

According to Carstensen (2021) from Foodxchange, the problem faced by smallholder urban farmers is a lack of knowledge about transportation planning and the creation of an optimal transport solution to execute produce deliveries within Gauteng province. A transportation solution plays a vital role in linking urban farmers to their customers.

4.1 Biographic data

4.1.1 Age groups

The majority of urban farmers (24%) are between the ages of 26 and 34, with 22% between the ages of 35 and 44. Thus, it appears as though the majority of urban farmers are middle aged. The middle-aged demographic has turned to urban farming to support or provide for their families. This could be for a variety of reasons, including unemployment or a lack of income. The smallest age cohort is composed of the 10% of respondents who are 65 years or older.

4.1.2 Education

According to the data gathered, the majority of urban farmers (57%) have a Grade 11 or lower education. Because many participants did not have the opportunity to complete their schooling, many chose urban farming to complement or replace their income. Only 23% of urban farmers surveyed have a matric certificate as their highest level. The remaining 20% have a post-matric qualification.

4.2 Farming data

4.2.1 Farming duration and type of farm

According to Figure 1, farmers who have been farming for four to six years are more likely to be community garden farmers than backyard and open land farmers. While those who have been farming for less than a year are considered backyard farmers.

Figure 1: Farming duration and type of farm

The longer people farm, the larger the scale of farming they seem to engage in. Open land farming has the most respondents who say that they have been farming for more than 15 years.

4.2.2 Packaging methods

The majority of smallholder urban farmers indicated that they utilised packaging. In total, 62% replied ‘Yes’; additionally, 28% claimed that they occasionally used packaging but did not specify when. Only 10% of respondents reported that they did not utilise any packaging at all. A total of 61% of respondents who indicated they package their produce did so with cardboard boxes, 14% used plastic bags, while another 13% used crates. Several respondents reported that they used more than one sort of packing material. Only 1% of respondents reported using a netting bag.

4.2.3 Produce sales

According to the survey, 36% of respondents sell their produce at farmers’ markets, which are often considered to be the most popular and easiest method of selling produce, while 22% sell straight from the farm. A total of 14% are informal traders who sell their products at informal markets, while a small percentage (6%) locate buyers through cold calling or social media platforms (11%).

Table 1: Produce sales

| Options | Frequency | Percentage |
|---------------------------------------|-----------|------------|
| Calls to potential customers | 5 | 6% |
| Online: WhatsApp, Facebook, Instagram | 10 | 11% |
| Informal trader | 12 | 14% |
| Farmers’ market | 31 | 36% |
| Retailers | 10 | 11% |
| Direct from urban farm | 19 | 22% |
| Total frequency (%) | 87 | 100% |

According to Table 1, markets and direct sales are the most popular and likely the simplest methods of selling, whereas marketing to individual customers is difficult and expensive, as marketing online and advertising require additional funds that may not be available.

4.3 Transportation data

4.3.1 Transportation alternatives

The majority (55%) of smallholder urban farmers are aware of outsourcing transportation options that would assist them in delivering their produce to customers, whereas 45% are unaware of such options.

4.3.2 Transportation companies utilised

According to the collected data, the vast majority of respondents (78%) use outsourced transportation providers to deliver their goods to their customers. Of the 78% of respondents who use outsourced transportation businesses to deliver their items to customers, 2% use online retailers similar to Takealot, 4% use The Courier Guy, 13% use Mr Delivery, and the bulk (52%) use other companies that were not identified. Only 22% of respondents who were aware of any outsourced transportation businesses do not make use of them.

4.3.3 Transportation applications

The feasibility of a transportation-based application that can be used by smallholder urban farmers for transportation of produce will be evaluated here.

According to Table 2, 66% strongly agree and agree that technology-based applications should be considered, whereas 12% strongly disagree and disagree; 22% remain neutral. According to the statistics, 67% strongly agree and agree that transportation applications will aid urban farmers in their delivery efforts, whereas 17% strongly disagree and disagree; 16% remain neutral. In total, 57% strongly agree and agree that they do not use transportation applications due to their perceived high cost, while 13% strongly disagree and disagree; 32% remain neutral.

Table 2: Outsourcing and application opinions

| Opinions | Strongly Disagree | Disagree | Neutral | Agree | Strongly Agree | Total (%) |
|--|-------------------|----------|---------|-------|----------------|-----------|
| Use transportation applications | 7% | 5% | 22% | 33% | 33% | 100 |
| Transportation application will assist in deliveries | 11% | 6% | 16% | 46% | 21% | 100 |
| Costly to use transportation applications | 6% | 6% | 32% | 19% | 37% | 100 |

Analysing the aforementioned data suggests that urban farmers are considering the use of technology applications and believe that they will aid them in their deliveries, but also believe that the cost of these applications is too expensive, and therefore they do not use them. According to the literature assessment, farmers who rely on their own vehicles have not yet considered an alternative.

4.3.4 Usage of private owned transportation

The majority of respondents (78%) use their own vehicle to deliver their produce to customers, while only 22% do not.

Figure 2: Usage of private owned transportation

The great majority (78%) of respondents, transport and deliver their produce to customers using their own vehicle. This demonstrates that the majority of respondents transport their produce to their customers using their own vehicles and do not rely on outsourced transportation.

4.4 COSTING DATA

4.4.1 Willingness to spend on outsourcing

In total, 30% of respondents are willing to spend between R21 and R40 rand, while 31% are willing to spend between R40 and R61 for transportation per delivery.

Figure 3: Transportation companies utilised

This demonstrates that, with the proper knowledge and subsequent willingness, urban farmers may be able to leverage outsourced transportation to grow their businesses and improve their effectiveness and efficiency.

4.4.2 Cost of utilising privately owned transportation

The possibilities of cooperative transportation systems that can provide cost-effective and efficient solutions for smallholder urban farmers will be investigated.

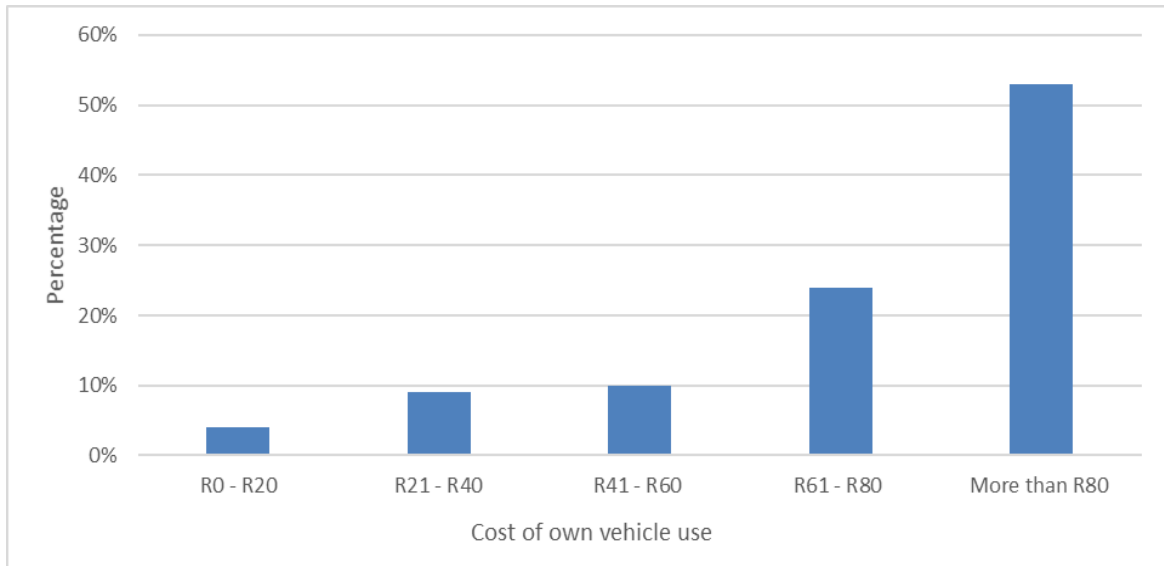

Figure 4: Cost of utilising privately owned transportation

Figure 4 demonstrates that the majority of respondents (53%) answered that it cost more than R80 for a delivery and 47% stated that it cost less than R80. Of the 47% of respondents who stated that it cost less than R80 per delivery, 24% stated that it cost between R61 and R80 per delivery, 10% stated that it cost between R41 and R60 per delivery, 9% stated that it cost between R21 and R40 per delivery, and 4% stated that it cost between R0 to R20 per delivery. According to this research, the majority of respondents (53%) pay more than R50 every delivery.

4.4.3 Losses due to damage and spoilage of produce in transit

The possibility of joint transportation solutions, which can aid the urban farmer to reduce produce loss will be explored.

Based on the collected data, the majority of the respondents (75,9%) indicated that they experienced damages and spoilage of the produce in transit. Whereas 24,1% of the respondents were not faced with the challenge of spoilage or damage of the produce while in transit.

4.4.4 Financial loss because of damage/spoilage.

The loss of produce owing to damage/spoilage has resulted in smallholder farmers losing money, as evidenced by the data obtained. In total, 26,4% of respondents reported losing between R0 and R200, 25,3% reported losing between R401 and R600, and 20,7% reported losing more than R801 worth of produce post-harvest and in transit.

Figure 5: Financial loss because of damage/spoilage

Produce damage/spoilage as a result of insufficient storage facilities and the absence of suitable vehicles for produce transportation is one of the difficulties faced by some smallholder farmers in Gauteng. Because fresh produce is particularly temperature sensitive, it is critical that post-harvest produce is properly stored and transported. Damage/spoilage of produce results in a financial loss, and some farmers cannot afford to lose a portion of their income.

5. CONCLUSION

The majority of smallholder urban farmers interviewed make use of their own vehicles to transport their produce to their customers and showed an interest in outsourcing transportation if it would be cheaper than using their own vehicle and would reduce delivery time. By analysing the data collected on assessing the knowledge that urban farmers have about the transportation options available to them, it was seen that 22% of urban farmers who responded have knowledge about outsourced transportation options; however, they do not make use of them. Findings also indicate that the farmers are in favour of third-party transportation with 66% of respondents saying that they are willing to use third-party transportation applications. In total, 67% said it would assist them in their business and make it more productive. However, 43% indicated they believed it would be more expensive and thus would not use the option.

Outsourcing transportation will benefit the smallholder urban farmers to reduce damage/loss of produce caused by unsuitable vehicles to deliver fresh produce. In addition, outsourcing transportation will reduce delivery time, which will result in preserved freshness of the produce as less time will be spent in transit. A trusted relationship may be established using the information provided by a third-party transportation provider, and urban farms can benefit from this option of outsourcing and become a more successful and efficient farm by filling the gap.

A cost-effective distribution network is thus crucial for smallholder urban farmers, but it is an area that has received insufficient attention for improvement, resulting in negative consequences for urban farmers due to income loss and delayed deliveries caused by lack of proper planning. Therefore, it would be feasible to do research on the consolidation and transportation of fresh fruit from smallholder urban farmers to their numerous consumers, allowing urban farmers to split the

cost of outsourced transportation, thereby reducing the number of empty loads. Further research can also be done on the third-party applications as smallholder urban farmers also showed interest in using application-based transportation companies as it would assist them in completing deliveries. However, there are still some reservations about using these applications due to their perceived high cost.

THE INFLUENCE OF STRATEGIC PARTNERSHIP, SUPPLIER INFORMATION SHARING AND INFORMATION QUALITY ON INTERNAL LEAN PRACTICES

T.M. Mofokeng

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

The importance of Small and Medium Enterprises (SMEs) is largely acknowledged in South Africa and yet the subject of internal lean practices has largely remained a research void within the sector. It is conceived that strategic partnerships allow firms to pool resources together for increased efficiency in internal lean practices while information-sharing and information quality facilitate the exchange of information and the transmission of constructive information respectively. Research into this conjecture, however, is scant and a number of SMEs remain frail with some continuing to deteriorate. This is disconcerting, given that an improvement in internal lean practices is one of the ways in which efficiency is guaranteed and likely so on the backdrop of strategic partnership, information-sharing and information quality collectively. Realising more efficiency in internal lean practices denotes cost reductions and an increase in revenue available for the firm's subsistence and sustainability. The current study therefore seeks to investigate the influence of strategic partnership, information-sharing and information quality on the internal lean practices of Small and Medium Enterprises (SMEs). The conceptualised research model and three hypotheses are empirically validated, using a sample of 350 SMEs from four provinces of South Africa i.e., Gauteng, North West, Free State, and Limpopo. The findings indicated that the research constructs' strategic partnerships, information-sharing and information quality influence internal lean practices in a positive way. Implications of the study are further provided.

Keywords: Strategic partnerships; supplier information sharing; information quality; internal lean practices; small and medium enterprises

1. INTRODUCTION

Internal lean practices are perceived to be important for the reason that they enable organisations to improve performance (Boyer, 1996; Swink, Narasimhan & Kim, 2005; Adamides, Karacapilidis, Pylarinou & Koumanakos, 2008; Shah, Chandrasekaran & Linderman, 2008; Fullerton & Wempe, 2009). According to Nurdiani, Börstler and Fricker (2016), lean practices strengthen a firm's capacity by enabling it to shorten lead times and provide quality products while minimising costs. More so, lean practices put emphasis on waste reduction (Altria, Dufton & Carleysmith, 2009), which supplements a firm's contribution to a green economy.

Internal lean practices are implemented as a way of responding to changes in the business environment. Since they are diverse (James-Moore & Gibbons, 1997; Cooney, 2002; Pettersen, 2009), they need to be controlled so that they remain within the best interests of the firm. To achieve this, buying firms should consider engaging in strategic partnerships with their suppliers. The advantage of such a partnership is that collectively, firms take the responsibility of improving operations and do so on a planned and tactical basis (Sadovnikova, Pujari & Mikhailitchenko,

2016). A partnership can further be supplemented by the exchange of information. Information-sharing, particularly if cooperative, stimulates coalition, increases learning and knowledge capacity and minimises the uncertainty of default in any process of improving efficiency (Raweevan & Ferrell, 2018; Piderit, Flowerday & Von Solms, 2011). The information transmitted between the buyer and the supplier also needs to be of the right quality. If improper information is shared, it will be misunderstood and misleading (Adams, 2003), thus conflicting with the objective of internal lean practice.

Internal lean practices are therefore implemented with the expectation of creating value. Firms are able to become more efficient while meeting consumer needs (Hines, Holwe & Rich, 2004; Gerbens-Leenes, Moll & Uiterkamp, 2003). However, success in internal lean practices is not typically candid (Sousa & Voss, 2008; Jayaram, Ahire & Dreyfus, 2010). This is because strategic partnerships are polarised while information-sharing and information quality are often mal-administered. Under these circumstances, the influence on internal lean practices is unconstructive. For example, the diversity in partnerships has been found to create conflict and impede lean practices from becoming effective (Sadovnikova *et al.*, 2016). Furthermore, insignificant information-sharing is said to increase insecurity and distorts its application (Ganesh, Raghunathan & Rajendran, 2008; Ketzenberg, Rosenzweig, Marucheck & Metters, 2007; Gal-Or, Geylani & Dukes, 2008; Mishra, Raghunathan & Yue, 2007; Jeong & Leon, 2012; Bian, Shang & Zhang, 2016) while low quality in information is conceived to subdue maximum effect, as these practices are effected on the basis of unconstructive data (Grudzien & Hamrol, 2016). This has been found to be typical of the SME sector (c.f. Offset, 2009; Lotfi, Mukhtar, Sahran & Zadeh, 2013; Haviernikova, Lemanska-Majdzik & Mura, 2017) and as disconcerting as this is, the influence of strategic partnerships, information-sharing and information quality on internal lean practices under the right circumstances has rarely been investigated. What is more, this conjecture identifies with the relational view which highlights that relational rents generated in inter-firm relationships are viable sources of competitive advantage (Dyer & Singh, 1998). For this reason and the expressed research gap, this study is therefore warranted. Three research questions are poised i. e:

- To what extent does strategic partnerships influence internal lean practices?
- To what extent does information-sharing influence internal lean practices?
- To what extent does information quality influence internal lean practices?

It is expected that findings will indicate if strategic partnerships, information-sharing and information quality are significant for internal lean practices in the SME sector. The rest of the paper is structured as follows: Section two involves a review on the literature while section three illustrates the conceptual model with hypotheses developed thereafter. Section four describes the methodology and design and conclusions are made in section five. Implications, and limitations and suggestions for future research are given in section six and seven respectively.

2. LITERATURE REVIEW

2.1 Theoretical Framework

2.1.1 Relational View

The relational view is an extension of the Resource-Based View (Dyer & Singh, 1998). The theory contends that competitive advantage derives from mutually adapted dyad relations and the

partner's collective input, which propel organisations to co-evolve and generate relational rents (Dyer & Singh, 1998; Lavie, 2006; Kamalaldin, Linde, Sjodin & Parida, 2020) or “the supernormal profit jointly generated in an exchange relationship that cannot be generated by either company in isolation and can only be created through the joint idiosyncratic contributions of the specific alliance partners” (Dyer & Singh, 1998:6). Notwithstanding competition between organisations as a general rule, firms that amalgamate their resources in a unique way may acquire greater advantage compared to competing firms incapable or unwilling to do so (Dyer & Singh, 1998). However, the inter-organisational competitive advantage is determined by *complementary resources and capabilities, relation-specific assets, knowledge-sharing routines and effective governance* (Dyer & Singh, 1998). Gronroos and Voima (2013) and Sjodin (2019) further add that the intimacy and quality of the relationship is central in co-creating this value.

Strategic partnerships are often complementary because the relationship has to be constructive. Resources and capabilities are pooled together and expended within the interest and goals of the partnership. What's more, the relational attributes (Sadovnikova *et al.*, 2016) reflect the relation-specific assets of the partnership. These can be production processes and systems (information technology) directly involved in creating value. According to Sadovnikova *et al.* (2016), strong control structures are critical for strategic partnerships in becoming effective. They minimise partner confusion, reduce role of uncertainty and streamline processes (Lambe, Morgan, Sheng & Kutwaroo, 2009) thereby effecting good governance. Information-sharing and information quality typify knowledge-sharing routines between the buyer and supplier. By default, information is shared in buyer-supplier relationships and over time, the routine evolves to exhibit properties of knowledge-sharing. This is because it allows both parties to eventually function better. Furthermore, it can be conceived that there is merit in knowledge-sharing routines when information is of the right quality.

2.2 Empirical Review

2.2.1 Strategic partnership

The inter-organisational literature identifies firm strategy, resources and relational characteristics as important aspects in partnerships (Sadovnikova *et al.*, 2016). This implies that firms must be compatible on each of these aspects. Cooperation has also been argued to be mandatory for strategic partnerships (Grant & Baden-Fuller, 2002) while at the same time, competition has been found to be integral as well (Ritala & Hurmelinna-Laukkanen, 2012; Sadovnikova *et al.*, 2016). Cooperation facilitates intense and comprehensive interactions and competition exists because the intentions of the partners may not be entirely compatible. Nonetheless, a strategic partnership in the context of lean is vital in that it maximises profits, minimises costs, facilitates better customer service and mitigates improbability (Zhao & Cavusgil, 2006; Sawhney & Zabin, 2002; Kothandaraman & Wilson, 2001; Hakansson, 1982). It is imperative that firms in a strategic partnership strive to co-exist and work together. However, Lado, Boyd and Hanlon (1997) assert that such a cooperation should always be encouraged with room for maximum innovative thinking.

As much as cooperation is essential in strategic partnerships, trust is just as important. Trust has been found to influence strategic partnerships by reducing partner opportunism and reinforcing teamwork (Sadovnikova *et al.*, 2016). In the literature, one definition of strategic partnerships is that they are long-term transactions, flows and linkages that occur among or between an

organisation and one or more organisations in the business environment (Oliver, 1990). The study, however, adopts a definition from Bachmann and Van Witteloostuijn (2006), who assert that strategic partnerships are “formal arrangements that bring together assets (of whatever kind, tangible and intangible) of two or more legally independent organisations with the aim to produce joint value added (of whatever kind, tangible or intangible)”. The construct is conceptualised contrarily to popular contexts that analyse strategic partnerships between economies (e.g., Yu, 2015; Romanova, 2016).

2.2.2 Information-sharing

In the main, information is shared vertically, horizontally or completely (Huang, Hung & Ho, 2017). Vertical information-sharing takes place between the buyer and the supplier while horizontal information sharing refers to that between buyers and buyers, sellers and sellers or even competitors and competitors. Complete information-sharing is a combination of both perspectives. It strives to increase the performance of supply chains and maximise overall profits (Li, 2002; Gal-Or, Geylani & Dukes, 2008; Rached, Bahroun & Campagne, 2015). The benefits are realised because the practice allows risk reductions and generates efficiencies (Mishra *et al.*, 2007; Ha *et al.*, 2008; Costantino, Gravio, Shaban & Tronci, 2015). The literature further adds that information-sharing fosters coordination (Disney, Lambrecht, Towill & Van De Velde, 2008; Cachon & Lariviere, 2005). This is important for internal lean practices generally grounded on the objective of removing waste and non-value added activities, standardising activities and instilling quality into the product as much as possible (Poppendieck & Poppendieck, 2003; Azadegan, Patel, Zangouinezhad & Linderman, 2013; Yang, Hong & Modi, 2011). However, according to Chu and Lee (2006) and Chen and Lee (2009), sharing information is meaningless if the cost of obtaining it is too high. This also would also contradict with the lean objective of minimising costs (Carter & Rogers, 2008).

It is important that the information shared with suppliers is done so under the right conditions. The purpose is therefore to add value through the exchange of knowledge (Cho, Bonn & Kang, 2016). Empirically, information has been found to improve firm performance (Bowersox, Closs & Stank, 2000; Cachon & Fisher, 2000). This effect has further been supported in a study by Grekova, Bremmers, Trienekens, Kemp and Omta (2014), which concluded that information sharing enhances the organisational ability to manage and adapt. The construct has served to mediate (e, g., Wu, 2008; Kim & Chai, 2017) in supply chain and business management studies as well, which further underscores its significance. By definition, it is generally regarded as surplus information about the business environment that is acquired directly through a partnership that improves the performance of that organisation (Yu, Yan & Cheng, 2001). This study, however, adopts a definition from Nooteboom (1999), Song, Berends, Van der Bij and Weggeman (2007), who assert that information sharing is “a transparent communication of information and the continuous sharing of explicit and tacit knowledge between the buying firm and the supplier”. Vertical information-sharing is therefore the construct’s context.

2.2.3 Information quality

Information is regarded as one of the most important resources of the organisation (Grudzien *et al.*, 2016). It is imperative that the information received is of the right quality in which lean practices are implemented. Information quality dimensions can be intrinsic or contextual

(McKnight, Lankton, Nicolaou & Price, 2017). Intrinsic information quality is the congruence between the data gathered and actual data in reality (Nelson, Todd & Wixom, 2005), while contextual information quality is a measure of the extent to which information contributes to completing a specific task effectively, for example, its relevance, completeness and predominance. According to Collier and Bienstock (2006), Chen and Kao (2010), and McKnight *et al.* (2017), this requisite is a motivating factor that allows both the buyer and supplier to excel in their roles respectively. In the context of lean, when information utilised is of the right quality, firms are stimulated and may benefit from accurate production schedules, improved inventory control and reduced operational costs (Lippert, 2007). The quality of information further amplifies the partners' level of cooperation and therefore overall operational performance (Madlberger, 2006). This is supported by Prakash (2011), who contends that quality information improves partner relationship and operational efficiency.

In some business relationships, quality is inadequate (Lippert, 2007; Nicolaou & McKnight, 2006). Lin and Lin (2006) cite accuracy and timeliness as especially poor. Information that has low quality can have severe consequences, including lost orders, increased claims from dissatisfied customers, and impaired reputation on behalf of the supplier (Guonaris, 2005; Mehta & Durvasula, 1998). Empirical studies, however, found that trust between the buyer and supplier is essential and helps in alleviating irregularities around information (e. g., Ibrahim & Ribbers, 2009; Nicolaou, Ibrahim & van Heck, 2013). Tests for mediation in the study by McKnight *et al.* (2017) confirmed that the influence of information quality on inter-firm relationships is strengthened by trust. Information quality is defined as “the merit or excellence of a system’s informational content” (Xu, Benbasat & Cenfetelli, 2013). This study, however, adopts a definition from McKnight *et al.* (2017), who assert that information quality is the extent to which information is useful in completing a specific task.

2.2.4 Internal lean practices

In general, the literature underlines two elementary orientations of lean practices: lean purchasing and lean operations (Mehra & Inman, 1992; Karlsson & Ahlstrom, 1997; Shah & Ward, 2007). Lean purchasing has an external orientation and is centred on minimising waste in the purchasing process (Freeland, 1991; Kaynak & Pagan, 2003). Comparatively, lean operations have an internal focus and are centred on reducing lot sizes and set-up times, eliminating equipment downtime, and producing quality while minimising costs (Gilbert, 1990; Poppendieck & Poppendieck, 2003; Li, Rao, Ragu-Nathan & Ragu-Nathan, 2005; Azadegan *et al.*, 2013; Nurdiani *et al.*, 2016). Given that an organisation is identified as a system, these two orientations are not mutually distinct (So & Sun, 2010). Internal lean practices have been considered to be solutions to problems relating to lead times, quality and costs (Leffingwell, 2007; Dybå & Dingsøy, 2008). However, to realise the benefit of internal lean practices optimally, firms promulgate its adoption through supply chain relationships (Perez, Castro, Simons & Gimenez, 2010). The buyer brings the supplier closer and collectively they engage in planning and problem solving (Li, Ragu-Nathan, Ragu-Nathan & Subba Rao, 2006) in which production pull systems, process improvement efforts, and preventive maintenance are some of the key practices (Shah & Ward, 2003; Furlan Pont & Vinelli, 2011). In the main, firms implement lean practices to improve performance while proactively shaping the environment (Boyer, 1996; Swink, Narasimhan & Kim, 2005; Adamides *et al.*, 2008; Fullerton *et al.*, 2009; Azadegan *et al.*, 2013). There has been an increase in the number of studies throughout

the years (Nurdiani *et al.*, 2016) and many of these report on the effect of lean practices on variables such as quality, finances and schedule (Project Management Institute, 2004). According to Fullerton, McWatters and Fawson (2003), improved firm performance can be identified in the form of an increase in customer service and market share. James *et al.* (1997), Cooney (2002) and Pettersen, (2009), however, assert that the effect of lean practices will depend on the environmental context of these firms (Jayaram *et al.*, 2010).

Wang, Huang and Dismukes (2004:1), Vonderembse, Uppal, Huang and Dismukes (2006:223) describe lean as an approach that aims at creating cost efficiencies through focusing on decreasing inventory, lead times and waste. In the present study, internal lean practices is a one-dimensional construct and is defined as “practices that aim to improve a firm’s internal production activities” (Shah *et al.*, 2003).

3. CONCEPTUAL MODEL AND HYPOTHESES DEVELOPMENT

Drawing from the relational view and the literature, a conceptual model was developed. Figure 1 below illustrates the formative conceptualised model. The study proposes that strategic partnership, information-sharing and information quality have an effect on internal lean practices. Three hypotheses are therefore drawn and will subsequently be developed.

Figure 1: Conceptual model

3.1 Hypotheses Development

3.1.1 Strategic partnership and internal lean practices

Sampson (2007) asserts that organisations collaborate to pursue certain projects, therefore firms form strategic partnerships when they seek to implement lean practices in their operations. Partnerships are considered to be essential because they directly impact performance (Hoang & Rothaermel, 2005). They are understood to creatively unite and synthesise their knowledge resources (Sadovnikova *et al.*, 2016) as well as streamline processes (Lambe, Morgan, Sheng & Kutwaroo, 2009).

For organisations to form partnerships when pursuing certain projects, it is likely that they do so as a response mechanism or a reaction. This implies that changes in customer needs, regulations, technology and competition compel responses and reaction from organisations. In other words,

changes within the business environment compel organisations to react by pursuing certain projects where strategic partnerships are required and necessary. Certain projects could be internal lean practices implemented by organisations. The study therefore proposes that there is a relationship between strategic partnerships and internal lean practices. In particular, it is conceptualised that strategic partnerships influence internal lean practices of Small and Medium Enterprises (SMEs). Therefore, it is hypothesised that:

H1: There is a positive relationship between the strategic partnership and internal lean practices of Small and Medium Enterprises

3.1.2 Information-sharing and internal lean practices

Firms implement internal lean practices to proactively shape the environment or as a response mechanism (Azadegan *et al.*, 2013). Sharing information therefore becomes vital and necessary as it is with the use of this information that organisations can respond successfully. According to Gilbert (1990), Poppendieck and Poppendieck (2003), Azadegan *et al.* (2013), Li *et al.* (2005) and Nurdiani *et al.* (2016), internal lean practices are constructive in that they reduce waste, minimise costs and simplify and standardise work activities while enforcing quality. However, to realise these outcomes, internal lean practices have to be implemented with the support of information-sharing between the buyer and supplier. It is emphasised in the literature that in addition to being well-informed for decision making, information-sharing is fundamental for alleviating irregularities and impelling progress and coordination (Ha *et al.*, 2008; Mishra *et al.*, 2007; Costantino *et al.*, 2015).

It is therefore proposed in the study that there is a relationship between information-sharing and internal lean practices. In particular, it is conceptualised that information-sharing has an influence on internal lean practices of Small and Medium Enterprises. Inferring from the literature and the observed evidence, it is therefore hypothesised that:

H2: There is a positive relationship between information-sharing and internal lean practices of Small and Medium Enterprises

3.1.3 Information quality and internal lean practices

Internal lean operations comprise systems that are information intensive (e. g., pull system) (Azadegan *et al.*, 2013). For this reason, the information that is used should be of the right standard of quality. Good quality information improves operations in the areas of production runs, costs and product quality (Lippert, 2007; Poppendieck *et al.*, 2003). If poor quality information is processed, there could be drastic consequences with regards to internal lean practices. McKnight *et al.* (2017) emphasise that trust is important if firms are to give and receive information of good quality. Therefore, for there to be information with adequate quality that significantly influences a firm's internal lean practices, there needs to be trust. Trust is important when processing information in order to avoid partner perceptions of uncertainty and risk, which compromise information quality (Ibrahim & Ribbers, 2009; Morgan & Hunt, 1994; Lippert, 2007; Nicolaou *et al.*, 2006; Nicolaou, Ibrahim & Van Heck, 2013; Ratnasingam, 2001).

The study therefore proposes that there is a relationship between information quality and internal lean practices. In particular, it is conceptualised that information quality has an influence on

internal lean practices of Small and Medium Enterprises. Deducing from the literature and the observed evidence, it is therefore hypothesised that:

H3: There is a positive relationship between information quality and internal lean practices of Small and Medium Enterprises

4. RESEARCH METHODOLOGY AND DESIGN

4.1 Sample and Data Collection

Research data was collected from the SME sector in four provinces of South Africa, i. e., Gauteng, North West, Free State, and Limpopo. These provinces were selected on the basis that the likelihood of depth and representation of the SME sector in South Africa is increased. A list of registered Small and Medium Enterprises was obtained from Companies and Intellectual Property Registration Office (CIPRO) from which a sample of 700 SMEs was extracted using simple random sampling. The survey method was used to collect data. Employees who held a managerial position in the operations department were requested to complete the questionnaire.

4.2 Measurement Instruments

Measures for all constructs, i. e., strategic partnership, information-sharing, information quality and internal lean practices were adopted from previous studies (see appendix). They were adapted to fit the study's context and purpose. All items were measured on a 5-point Likert scale.

5. DATA ANALYSIS AND RESULTS

5.1 Sample Description

Of the 700 questionnaires distributed, 350 questionnaires were usable, representing a response rate of 50%. Results pertaining to the profile of respondents are indicated as follows: of the 350 firms, 104 were sole proprietors while the least (26) were cooperatives; 105 responses were from the retail industry and 127 firms had a number of employees within the range of 20-50. Most SMEs have been in operation for five to ten years and, in general, a significant number is located in the Gauteng province.

5.2 Structural Equation Modelling using Smart PLS

A structural equation modelling (SEM) approach, using Smart PLS statistical software (Ringle, Wende & Will, 2005) was adopted for the purpose of analysing the data. A mandatory two-stage procedure of SEM was carried out (Anderson & Gerbing, 1988). First, measurement model assessment was performed to test for reliability and validity. In the second stage, structural modelling was undertaken to evaluate the causal relationships between constructs. Results from this two-staged procedure are discussed in detail below. Table 1 below exhibits the results from the scale accuracy analysis.

Table 1: Scale accuracy analysis

| Research Construct | | Descriptive Statistics | | Cronbach's Test | | CR Value | AVE Value | Factor Loading |
|-------------------------------|------|------------------------|-------|------------------------|----------------|----------|-----------|----------------|
| | | Mean | SD | Item-total correlation | α value | | | |
| Information-Sharing (IS) | IS1 | 2.89 | 1.402 | 0.570 | 0.905 | 0.884 | 0.718 | 0.900 |
| | IS2 | 3.03 | 1.478 | 0.782 | | | | 0.915 |
| | IS3 | 3.02 | 1.507 | 0.760 | | | | 0.934 |
| Information Quality (IQ) | IQ1 | 2.64 | 1.394 | 0.623 | 0.836 | 0.902 | 0.755 | 0.804 |
| | IQ2 | 2.43 | 1.373 | 0.605 | | | | 0.913 |
| | IQ3 | 2.29 | 1.293 | 0.534 | | | | 0.885 |
| Strategic Partnership (SP) | SP1 | 2.64 | 1.394 | 0.623 | 0.859 | 0.914 | 0.779 | 0.879 |
| | SP2 | 2.43 | 1.373 | 0.605 | | | | 0.880 |
| | SP3 | 2.29 | 1.293 | 0.534 | | | | 0.889 |
| Internal Lean Practices (ILP) | ILP1 | 2.07 | 1.227 | 0.578 | 0.804 | 0.884 | 0.718 | 0.799 |
| | ILP2 | 2.51 | 1.542 | 0.717 | | | | 0.884 |
| | ILP3 | 2.53 | 1.312 | 0.539 | | | | 0.857 |

Note: IS = Information-sharing; IQ = Information quality; ILP = Internal lean practice; SP = Strategic partnership
SD = Standard Deviation CR = Composite Reliability AVE = Average Variance Extracted

* Scores: 1 – Strongly Disagree; 3 – Moderately Agree; 5 – Strongly Agree

5.2.1 Measurement model assessment

At the outset, reliability of the measurement scale was ascertained through running Cronbach alpha tests. Alpha coefficients ranged between 0.804 and 0.905, which connoted reliability as per the recommended ≥ 0.7 threshold (Green & Salkind, 2017). Tests for composite reliability were further performed to validate reliability (Chinomona, 2011). Results indicated internal consistency as CR indexes presented in Table 1 levelled at values greater than 0.6 (Chinomona, 2011). Validity was examined hereafter. This was initiated by determining convergent validity through examining if items loaded well on their respective (a priori) constructs that is if the value is ≥ 0.5 (Anderson & Gerbing, 1988; Chinomona, 2011; Sarstedt, Ringle, Smith, Reams & Hair, 2014). Results indicated that all measurement items loaded strongly on their common constructs (0.799-0.934), expressing that each measured at least 50% of their respective constructs (Anderson & Gerbing, 1988; Chinomona, 2011). Furthermore, tests for the Average Variance Extracted confirmed that all constructs were represented well by their measurement items as they exhibited estimates (0.718-0.779) greater than 0.5 respectively (Fraering & Minor, 2006; Sarstedt *et al.*, 2014). In verifying validity even further, discriminant validity was assessed. First, it was determined if there were any significant inter-construct cross-loadings by examining if correlation coefficients do not exceed 1 (Chin, 1998; Chinomona, 2011). Once that was confirmed, the square root of each AVE was compared against correlation coefficients and the resulting higher indexes in favour of the former affirmed the presence of discriminant validity (Zait & Berteau, 2011). Results from testing discriminant validity are presented in Table 2 below.

Table 2: Correlation between the constructs

| Research constructs | Construct Correlation | | | |
|-------------------------------|-----------------------|--------------|--------------|--------------|
| | SIS | IQ | SP | ILP |
| Information- Sharing (IS) | 0.847 | | | |
| Information Quality (IQ) | 0.529 | 0.869 | | |
| Strategic Partnership (SP) | 0.339 | 0.290 | 0.883 | |
| Internal Lean Practices (ILP) | 0.632 | 0.605 | 0.430 | 0.847 |

Note: SP = Strategic Partnership; IS = Information Sharing; IQ = Information Quality; ILP = Internal Lean Practices

5.2.2 Structural model results

Figure 2 and Table 3 present results from structural modelling. According to Chin (1998), the standardised path coefficients are expected to be at least 0.200 and preferably greater than 0.300. Bootstrapping (300 re-samples) was used to evaluate the reliability of each coefficient. The results provide support for all the three hypotheses. All path coefficients were above 0.2 and significant at least at pb 0.001. As indicated in Figure 2 and Table 3, the path coefficients are 0.201, 0.381 and 0.345 for Hypothesis 1, Hypothesis 2 and Hypothesis 3 respectively.

Table 2 further presents *t*-statistics and P values. *T*-statistics were measured against a threshold of ≥ 1.96 while P value tests were undertaken at a ≤ 0.05 significance level (i. e., 1-95%) to avert false positives (Kock, 2016). All three hypotheses were positive and significant. These results further validated statistical significance and support for hypothesised relationships.

Figure 2: Structural model

Note: SP = Strategic Partnership; IS = Information-Sharing; IQ = Information Quality; ILP = Internal Lean Practices

Overall, R^2 indicate that the research model explains more than 50% of the variance in the endogenous variable. Having employed the formulae provided by Tenenhaus, Vinzi, Chatelin and Lauro (2005), the global goodness-of-fit (GoF) statistic for the research model was examined and identified at 0.38, which exceeds the threshold of >0.36 suggested by Wetzels, Odekerken-Schröder and Van Oppen (2009). Thus, this study concludes that the research model has a good overall fit.

Table 3: Results of structural equation model analysis

| Path | Hypothesis | Path coefficients (β) | T - Statistics | P - Values |
|--|------------|-------------------------------|----------------|------------|
| Strategic partnership (SP) \rightarrow Internal lean practices (ILP) | H1 | 0.201 | 2.829 | 0.005 |
| Supplier information sharing (SIS) \rightarrow Internal lean practices (ILP) | H2 | 0.381 | 4.210 | 0.000 |
| Information quality (IQ) \rightarrow Internal lean practices (ILP) | H5 | 0.345 | 3.680 | 0.000 |

Note: SP = Strategic Partnership; IS = Information-Sharing; IQ = Information Quality; ILP = Internal Lean Practices

6. DISCUSSION AND CONCLUSIONS

The purpose of the study was to investigate the influence of strategic partnership, supplier information sharing and information quality on internal lean practices. The relational view was adopted as the study's theoretical framework. Three hypotheses were developed and examined with the use of data collected from small and medium enterprises in four provinces of South Africa i. e., Gauteng, North West, Free State, and Limpopo. Inferring from the empirical results, all hypothesised relationships were supported and found to be significant as well.

It is important to note that information-sharing strongly influenced internal lean practices (0.381) more than strategic partnership (0.201) and information quality (0.345). This result is surprising as it is accepted that strategic partnerships and information quality allow firms to be synchronised and collaborate well and utilise information that provides value. Perhaps the reason for this is, like most firms, SMEs are reluctant to engage in partnerships and share information that is quality because of the vulnerability and exposure of company strategies and processes that come with partnering and sharing a pedigree of information. Trust is therefore an important requirement as underscored by Sadvnikova *et al.* (2016). It is also paradoxical that information-sharing (0.381) has a more significant effect on internal lean practices given that this practice essentially involves sharing information and conceivably that which is constructive. Perhaps the logic behind this is that in any of its applications, information-sharing is expansive and orientated to improve organisational performance in the general (Grekova *et al.*, 2014) in contrast to information quality which is centred on data and the extent to which information helps an organisation to complete specific tasks (McKnight *et al.*, 2017).

7. IMPLICATIONS OF THE STUDY

The current research is the first to examine these hypotheses with the use of data collected from SMEs in four provinces of South Africa, and findings have provided some educational implications. On the academic side, the study contributes significantly to the literature of lean practices in the Small and Medium Enterprise sector. In the main, results corroborated the proposition that strategic partnership, information-sharing and information quality have an effective impact on internal lean practices. Additionally, the study's adoption of the relational view proved to be informed and practical. This denotes that the relational view supports and validates SME internal lean practices as relational rents generated from buyer-supplier interactions (strategic partnership, information-sharing, information quality). Overall, the study is expected to further increase our understanding of internal lean practices within the SME sector, which is an important but often much neglected research context of the SME sector in developing countries in Southern Africa.

From the viewpoint of the practitioner, the important role of strategic partnerships, information-sharing and information quality on internal lean practices is highlighted. SME owners and their managers are therefore advised to heed these findings in planning and decision-making. The following are further recommended: first, it is important that firms, particularly SMEs, embrace information-sharing in the context of internal lean practices and do so under the right conditions. Given that vertical information sharing is a priori, suppliers are and should be prioritised as an extension of the buying firm. In light of this and the results, SMEs must concede and acknowledge sharing information with the supplier as key to effective internal lean practices. Supplier

information is an invaluable resource and should be leveraged for gains that extend even beyond internal lean practices. Second, SMEs should always strive to share and make use of information that is accurate, reliable and up to date. This would minimise irregularity and maximise efficiencies in tasks performed in internal lean practices. Despite the insignificant relationship found between strategic partnerships and internal lean practices, such a collaboration must remain an objective. Firms must acknowledge that strategic partnerships are built over time and patience is required. Once trust has been developed, it can be accepted that its influence on internal lean practices will be more significant.

8. LIMITATIONS AND FUTURE RESEARCH

The study is not without limitations. First, the study is confined to SMEs in four out of nine provinces in South Africa and as such, representation of the SME sector in the country is weak. It would be progressive if future studies could conduct a similar study with data collected from more provinces. In addition, extending the study to other African countries would impart a different point of view that further contributes to the literature.

Second, self-ratings of the study's constructs were collected from SMEs. The results would be more telling if data from both sides of the dyad i. e., SMEs and their suppliers were compared. Future studies could, therefore, be an extension that analyse paired data from both the SMEs and their suppliers. Third, trust was found to be relative to all three predictors. Future research could therefore expand the study's conceptual model to include trust as an additional construct. Since this study did not check the common method bias, it is advised that future researchers attend to this.

B.A. Mokoena

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

It is evident that social media has become a fundamental instrument in society and has revolutionised the way society interacts and conducts business. However, many challenges are associated with social media concerning the affordability and accessibility of the internet. Consequently, it makes it a challenge for organisations to utilise social media as a reliable marketing instrument. Therefore, the study seeks to examine the effect of social media marketing dimensions on consumer attitudes among Generation Y consumers.

The sample consisted of 285 self-reporting social media active users located in the southern Gauteng region of South Africa. The study adhered to a quantitative approach and a snowball sampling method was utilised to collect data. A positivist research philosophy was followed whereby hypotheses were formulated for the study. In addition, formal procedures regarding research ethics were observed during empirical data collection and the questionnaire was also tested for reliability as well as validity. A pilot study preceded the main data collection survey processes. The regression model revealed that social media marketing dimensions (informativeness, source credibility and perceived enjoyment) predict a significant effect on consumers' attitude towards social media marketing. The empirical results regarding an existence of a relationship between the other social media marketing dimension (social identity) and consumers' attitude did not yield a statistically significant relationship in the regression model. As such, insight acquired from this study will assist both marketing academics as well as practitioners in comprehending Generation Y consumers' perceptions on attitudes in relation to the adoption of social media as a marketing instrument. Based on the results, recommendations assert that, among others, marketing practitioners should effectively adopt social media as a marketing platform to communicate their marketing efforts and initiatives. Furthermore, marketers should integrate their marketing initiatives and strategies with the 4th industrial revolution. In addition, limitations and future research avenues are identified and the contributions of this study are discussed.

Keywords: Informativeness, perceived enjoyment, source credibility, social identity, consumer attitudes, Generation Y

1. INTRODUCTION

Hays, Page and Buhalis (2014:304) define social media as deeds, actions and operations among groups of people who gather online to exchange information, understanding and feelings by utilising conversational media. Therefore, social media is initiating a new system of how society absorbs and contributes to the design of information. The emergence and acceptance of social

network sites have established a new social order of alliance and communiqué, where social network platforms are the fundamentals of the new digital existence and society has formed a digital existence, almost without realising it.

The development of social marketing as an academic field of study has been fuelled by the extensive usage of social media marketing as a state of art methodology to stimulate behaviour change and the appreciation by many governments that it contributes significantly to enhanced digital existence of consumers and societies (Truong & Dietrich 2017:1). Guesalaga (2016:72) defines social media marketing as the technological component of the communication, transaction and relationship building functions of a business, which leverages the network of customers and prospects to promote value co-creation. 77 percent of the inspected US corporations are estimated to be utilising social media for marketing purposes (Pan, Vorvoreanu & Zhou 2014:347). Executives spend time on social media marketing to nurture relations and engage with customers (Vries, Gensler & Leeftang 2012:83). Furthermore, Constantinides (2014:42) affirms that to effectively engage social media as part of the corporate marketing strategy, it needs to demonstrate an exceptional company website that is well designed, competent and credible, organisationally united and customer orientated. The organisation's existence towards social media marketing must reproduce and clearly communicate its positioning, excellence, customer orientation and appearance (Seo & Park 2018:37). In addition, the acceptance of social media marketing is influenced by consumer attitudes.

Boateng and Okae (2015:250) define consumer attitude as an individual's favourable or unfavourable assessment with using a service. In contrast, Khandelwal and Bajpai (2013:90) define consumer attitude as the trend of group affiliates to establish a group norm and the tendency of individuals to comply with the respective norm. In addition, consumer attitudes towards social media marketing can be defined as consumers' likes or dislikes of marketing initiatives communicated through social media platforms (Duffet 2017:498). Ling, Piew and Chai (2010:118) state that in consumer studies, consumer attitude constitutes the central role because it influences feelings, thoughts and above all the process of consumer decision making. Furthermore, consumer attitude can be a determinant in the decision-making process of adopting a technological innovation.

Generation Y consumers are defined as individuals born in the 1980s and 1990s and have grown up in a materialistic society with social media (Kim & Jang 2014:39). Bolton, Parasuraman, Hoefnagels, Migchels, Kabadayi, Gruber, Loureiro and Solnet (2013:248) articulate that Generation Y consumers grew up with a technological device and have understood its use for numerous roles in their lives, mostly communication. According to Lissitsa and Kol (2016:305), Generation Y individuals originated during the period of economic development, strong exposure of social media and the disappearance of modern beliefs, sustained by globalisation and strong domination from western culture. According to Statistics South Africa (2020:1), there is an estimated more than 27 percent of the South African population identified as Generation Y, translating into a buying power of 14 million people. In other words, Generation Y consumers are an important market to target in relation to the social media, as a marketing channel.

2. LITERATURE REVIEW

The literature review is focused on the selected social media marketing dimensions that may have the inclination to enhance Generation Y consumer attitudes.

2.1 Informativeness

Informativeness is defined as the ability of advertising to inform users of alternative product information, which allows them to make choices with the highest value (Hamouda 2018:428). The key inspiration for Social Network Service (SNS) is the trade of reliable data, given the information structure of their SNS. Celik and Karaaslan (2014:304) define SNSs as software technology services that offer users modified facilities, such as constructing a digital existence, locating users with whom a mutual connection is shared, seeing and permitting their list of networks and information from other users in the allowance of the system. SNS users were found to be friendly to information when advertising on social network platforms and indeed, informativeness remained positively associated to consumer' attitude towards advertising on social network platforms (Bright, Gangadharbatla & Logan 2010:168). Vries, Gensler and Leeflang (2012:85) affirm that information exchange is a crucial motive for individuals to engage in social networking platforms, contribute to an online community and participate in Facebook groups.

Based on the preceding argument, the following hypothesis is proposed:

H1: Informativeness significantly influences Generation Y consumer attitudes

2.2 Source Credibility

Source credibility is defined as the positive features of the source of the communication that persuades how a receiver responds to the message (Todd & Melancon 2018:81). Source credibility refers to a source's capability and rationale to offer correct and honest information and the source of influential information is valued as more reliable through knowledge or trustworthiness (Chiou, Hsu & Hsieh 2013:912). Reliable data sources usually produce enough influential messages and prompt a satisfactory attitude towards products or services. Housholder and LaMarre (2014:370) advocate that conceptual reliable sources comprise two main components, character and capability (such as dependability and capability), therefore, sources are reliable (or trustworthy) to a degree that the audience are convinced that their declarations are valid. Luo, Luo, Schatzberg and Sia (2013:93) state that source credibility can directly change an individual's attitude and that a highly credible source will provide a greater impact on information credibility, hence individuals are more likely to accept and adopt the viewpoint of the information communicated. Furthermore, Luo, Luo, Schatzberg and Sia (2013:93) state that source credibility can directly change an individual's attitude and that a highly credible source will provide a greater impact on information credibility, hence individuals are more likely to accept and adopt the viewpoint of the information communicated.

The following hypothesis is then set for the study:

H2: Source credibility significantly influences Generation Y consumer attitudes

2.3 Perceived enjoyment

Perceived enjoyment is evaluated as a form of amusement, desire or enthusiasm resulting from performing an activity (Than, Goh & Lee 2015:595). According to the 14th Bled Electronic Commerce Conference compiled by Heijden (2001:177), perceived enjoyment is defined as the degree to which the deed of utilising software technology is alleged to be fun in its own capacity and separate from any performance drawbacks that may be projected. Perceived enjoyment is theorised to have an influential effect on usage intention. Therefore, perceived enjoyment refers to a consumer's view that a service rendered is fundamentally enjoyable (Yen 2014:581). Consequently, perceived enjoyment reflects the satisfaction and pleasure related to utilising a technological innovation such as social media marketing (Zhou 2013:1290). Furthermore, regarded as an essential element, perceived enjoyment has been thoroughly scrutinised and its impact on consumers' attitude and behaviour has been investigated by a variety of studies (Than, Goh & Lee 2014:91).

Based on the preceding argument, the following hypothesis is proposed:

H3: Perceived enjoyment significantly influences Generation Y consumer attitudes

2.4 Social identity

Langner, Hennigs and Weidmann (2013:32) define social identity as an individual's awareness that he/she belongs to a particular social group together with emotional and significance of the group membership. Therefore, social identity articulates how belonging to a group shapes individual behaviour, as it claims that individuals describe themselves as associates of groups and develop their identity group affiliation. Kwon and Wen (2010:256) assert that "social identity theory has recently expanded from its origins in social psychology to areas of organisational research". Social identity is described by its consensus to the social group in accordance with in-groups (individuals that belong to the same virtual community) and discrimination against out-groups (individuals that do not belong to a virtual community). Individuals who possess a high social identity tend to declare their in-groups in ways that distinguish themselves clearly from out-groups and prefer a group which provides them with positive online existence (Langner, Hennigs & Weidmann 2013:33). In a nutshell, Pan, Lu, Wang and Chau (2017:76) articulate that social identity refers to the classifications of the self that reflect integration to more inclusive social units. Consistent with this, Ambrose, Matthews and Rutherford (2018:271) also contend that social identity suggests that individuals normally categorise themselves into a variety of classifications as a means of determining their identity and belonging to a larger collective.

Based on the foregoing arguments, the following hypothesis is proposed:

H4: Social identity significantly influences Generation Y consumer attitudes

2.5 Consumer attitudes

Consumer attitudes can be defined as individuals' total assessment of carrying out a specific conduct (Matikiti, Mpinganjira & Lombard 2017:3). Consumers' attitudes towards social media marketing in general can be described as unfavourable or favourable tendencies towards marketing communications through social media (Humbani, Kotze & Jordaan 2015:5). Dhurup, Muphosi and Shamhuyenhanzva (2015:1273) define consumers' attitudes as a psychological act that is

articulated by an evaluation of a specific entity with a certain extent of disfavour or favour. Ariffin, Aun and Salamzadeh (2018:35) attest that attitude is the tendency or trend to act in a negative or positive manner to a given motivation such as a brand, product category and advertisement. Similarly, Bashir and Madhavaiah (2015:79) define consumer attitude as practised tendencies to react in a consistently unfavourable or favourable way with detail to a given object.

According to Wang, Zhang, Choi and Eredita (2002:9), individuals form an attitude towards an object in relation to affective beliefs in a component that reflects how they feel about the object and, on the other hand, to cognitive beliefs in a component that reflects whether the aspects and functions of the object are to their advantage. In addition, the more an individual's attitude is favourable towards a brand or service, the more likely they are to utilise the service.

3. METHODOLOGY

3.1 Research design

According to Pallant (2016), research design refers to a mind map that outlines in detail the process the study will follow by outlining procedures for the collection of data and analysis applicable to the research study under observation. A quantitative research approach using a survey was found to be more suitable in this study because of the nature of the topic, population size and large-scale numerical data collected that needs to be analysed by means of statistical procedures. For the purpose of this study, a descriptive research design was deemed appropriate in order to quantify the different social media marketing activities. Furthermore, a quantitative research approach a quantitative research approach was deemed appropriate for this study. The rationale for employing this approach is that it enables the researcher to quantify the data and generalise the results from the sample to the population of interest (Zikmund & Babin 2007).

3.2 Sampling method

The purpose of the study, availability of resources and type of research design followed influenced the choice of a sampling method in this study. Due to the quantitative nature of the study, a non-probability sampling method was utilised, specifically the snowball sampling technique, as it enables the selection of respondents based on a series of referrals (Chowdhury *et al.* 2013). The major advantage of the snowball sampling technique is that it substantially increases the likelihood of locating the desired characteristics in the population (Malhotra 2010).

3.3 Research instrument and data collection procedure

The researcher made use of a self-administered structured questionnaire to collect data. A questionnaire was preferred as a measuring tool mainly because it is simpler to administer and eases the variability in the outcomes that may be instigated by dissimilarities in other types of interviews (Malhotra 2010). Due to resource constraints, this study adopted existing scale items from past related studies, which assisted the researcher to make validity and reliability comparisons with variables utilised in previous research. A survey questionnaire adapted from previous studies was used and comprised of six sections. Section A solicited demographic variables, while sections B to F on the study constructs were varied, using a five-point Likert and semantical differential scales to address issues of common method bias in scale construction. Section B solicited information on source credibility in the context of social media marketing

adapted from Mahapatra and Mishra (2017). Section C consisted of statements relating to informativeness in the context of social media marketing adapted from Logan, Bright and Gangadharbatla’s (2012). Section D focused on gathering information on perceived enjoyment in the context of social media marketing and was adapted from Soares and Pinho’s (2014). Section E focused on social identity in the context of social media marketing and the questions were adapted from a questionnaire that was prepared by Chahal and Rani (2017). Questions to solicit information on consumers’ attitude towards social media marketing (Section F) were adapted from a questionnaire developed by Akar and Topcu (2011). Furthermore, the sections of the study constructs were varied, using a five-point Likert and semantical differential scales to address issues of common method bias.

3.4 Statistical analysis

Data were captured on Microsoft Excel, whereby a coding book was established and then transferred to Statistical Package for Social Sciences (SPSS) version 26.0. SPSS performed descriptive and inferential statistics (comprising correlations and regression analysis).

4. RESULTS

4.1 Sample composition

There was an unequal distribution of female (n=156; 55%) and male (n=130; 45%) respondents in the sample. The majority of the respondents indicated being single (n=247; 86.6%) and earning a monthly income ranging between R10 000 - R20 000 (n=150; 52.4%) as well as spending more than R1 000 on social media activities (n=180; 64%).

4.2 Correlation analysis

The purpose of this analysis is to discover whether two or more variables are in some way associated with one another (Leedy & Ormond 2021).The study utilised Pearson’s correlations analysis as reported in Table 1.

Table 1: Inter-construct correlations, descriptive statistics and reliabilities

| Construct | SC | IN | PE | SI | CA | MEAN S | STD DEV | Cronbach alpha |
|-----------|--------|--------|--------|-------|------|--------|---------|----------------|
| SC | 1.00 | | | | | 4.02 | 0.429 | .664 |
| IN | .478** | 1.00 | | | | 4.30 | 0.375 | .664 |
| PE | .199* | .092 | 1.00 | | | 3.87 | 0.418 | .764 |
| SI | .469** | .405** | .154* | 1.00 | | 4.15 | 0.443 | .607 |
| CA | .257** | .278** | .214** | .179* | 1.00 | 4.31 | 0.323 | .635 |

Key: SC= Source credibility, IN= Informativeness, PE= Perceived enjoyment, SI= Social identity, CA= Consumer attitudes **Correlation is significant at the 0.05 level (2-tailed)

An analysis of the correlation matrix indicates significant positive associations between the research constructs.

4.3 Reliability and validity

The Cronbach’s coefficient alpha was used to assess the internal consistency of each construct employed in the study and the accuracy of the questionnaire. The results of the study reported in Table 1 show that all constructs, attained Cronbach alpha values that were above 0.6, which attests

that the scales met the minimum recommended threshold and were reliable. In order to determine the degree that a measuring scale precisely measures what it was supposed to measure, various validity procedures were undertaken to the measuring instrument. Face and content validities were tested through a review of the questionnaire by subject experts in the marketing field. A pilot study was undertaken to access construct validity. In this study, convergent validity was determined through the Cronbach alpha coefficient that were greater than the recommended level of 0.60 as well as significant positive correlation coefficients reported in Table 1. Average inter-item correlation coefficients are all above and Watson’s (1995:316) recommended range of 0.15 to 0.50, suggesting existence of discriminant validity for each of the scales used in the study.

4.4 Regression analysis

Regression analysis is a procedure for analysing associate relationships between a metric-dependent variable and one or more independent variables (Malhotra, Nunan & Birks, 2017). Prior to the computation of the regression model, it was necessary to assess whether the data set posed any multicollinearity problems. Multi-collinearity was assessed by inspecting the tolerance value (Tol) (>0.1) and the variance inflation factor (VIF) (<10) for each construct. As shown in Table 2, all the independent variables had VIF values of <10 and tolerance value of >0.10, thus dispelling any multicollinearity threat (Malhotra, 2010). Regression analysis was then performed and the results are recorded in Table 2. In the regression model, CA was entered as the dependant variable while the four predictors (Sc, IN, PE and SI) were entered as independent variables.

Table 2 Regression model

| DEPENDENT VARIABLE: Consumer attitudes | Standardise d Beta | T | Sig | Collinearity statistics | |
|---|-----------------------|-------|-------|-------------------------|-------|
| | | | | Tol. | VIF |
| Independent variables | | | | | |
| (Constant) | | 9.889 | | | |
| IN (H1) | .171 | 2.767 | .008 | .667 | 1.499 |
| SC (H2) | .302 | 6.030 | .003 | .729 | 1.371 |
| PE (H3) | .169 | 2.956 | .003 | .955 | 1.047 |
| SI(H4) | .017 | 0.256 | 0.798 | .734 | 1.362 |

R = 0.354 R² = 0.125 Adjusted R² = 0.113 F change 10.042 **sig at <0.05. Tol. = Tolerance value, VIF = Variance inflation **SC**= Source credibility, **IN**= Informativeness, **PE**= Perceived enjoyment, **SI**= Social identity, **CA**= Consumer attitudes

Overall, the four predictor variables (I, SC, PE and SI) accounted for approximately 11 percent (Adjusted R² = 0.113) of the variance in CA. These results indicates that CA is attributed to the combined effect of the four predictors

5. DISCUSSION OF RESULTS

5.1 Descriptive statistics

With respect to descriptive statistics, Table 1 indicates that all the mean scores returned for all the constructs were all above the score of three on the Likert scale (>3 - <5) suggesting that the respondents recognise the significance of these constructs within the retail outlet. The standard deviations were less than one, therefore, indicating that the mean values are correct reflection of the majority average perceptions.

5.2 Correlations

The results of the correlation analysis showed a significant weak positive association between source credibility and consumer attitudes ($r=0.257$; $p<0.05$). These results suggest that an increase in source credibility might trigger an improvement in consumer attitudes towards social marketing adoption among Generation Y consumers. There was a significant yet weak positive association between informativeness and consumer attitudes ($r=0.278$; $p<0.05$). This result implies that an increase in informativeness among Generation Y consumers may slightly improve their attitudes towards social marketing adoption. Further analysis of the correlation matrix indicates a significant weak positive association between perceived enjoyment and consumer attitudes ($r=0.214$; $p<0.05$). This indicates that as perceived enjoyment increases among Generation Y consumers, they might experience a positive attitude towards social marketing adoption. Finally, the results of the correlational analysis, revealed a positive yet weak association between social identity and consumer attitudes ($r=0.179$; $p<0.05$) suggesting that a positive relationship exist between social identity and consumer attitudes towards social marketing adoption among Generation Y consumers.

5.3 Regression

Informativeness recorded the weakest but statistically significant influence on consumers' attitude in the regression model ($\beta=+0.302$; $t=6.030$; $p<0.05$). The results are in line with the research findings of Lee and Hong (2016) who also reported existence of a significant influence of informativeness on consumers' attitude. As a result, H1 can be accepted.

The second hypothesis intended to test the influence of source credibility on consumers' attitude towards the adoption of social media marketing. The results acquired from the hypothesis testing ($\beta=+0.171$; $t=2.767$; $p<0.05$), corroborated the assertion by Wu and Wang (2011), that source credibility has a positive influence on consumers' attitude. Therefore, a decision was taken to accept H2 accordingly.

In relation to the third hypothesis, perceived enjoyment was found to have a significant influence on consumers' attitude ($\beta=+0.169$; $t=2.956$; $p<0.05$). To this end, a statistically informed decision was undertaken to accept H3.

With respect to the fourth hypothesis, the sample data could not establish enough evidence for the relationship between social identity and consumers' attitude ($\beta=0.017$; $t=0.256$; $p>0.05$). In this regard, H4 is rejected since there is inadequate evidence to support the acceptance of the fourth hypothesis suggested between social identity and consumer attitudes.

6. LIMITATIONS AND IMPLICATIONS FOR FURTHER RESEARCH

With regards to the scope, the study concentrated only on Generation Y consumers' who are based and reside in the southern Gauteng region. To increase the scope for a comprehensive picture of Generation Y consumers', it would be of interest to concentrate on other provinces and regions inclusive of South Africa. Furthermore, the study utilised a snowball sampling method which is not based on any probability estimation and thus dispenses implications for sampling error and thus have the potential to contaminate the findings. Future research should be conducted using sampling methods which are probabilistic in nature in order to permit statistical estimations. Another limitation is attributed to the use of a single method of data collection (data were collected

quantitatively). Resultantly, the study did not acquire the benefits of conducting mixed or triangulation methods approach. Nevertheless, it will be worthwhile for future researchers to utilise both quantitative and qualitative paradigms to supplement each other.

7. CONCLUSION

The study has provided relevant and significant findings with regards to understanding Generation Y consumers' behaviour and attitude in relation to social media marketing adoption. These are new types of influential and refined customers developing, which are difficult to control, convince and retain (Constantinides 2014:40). However, the study was predisposed to several limitations, which provided a foundation in relation to opportunities for further research in the future. Drawing from the findings of this study, it is evident that the 4th industrial revolution has dawned and social media has become an integral part of our lives. It was further established in this investigation that the adoption of social media marketing is influenced by an assortment of elements. Finally, the study provides insights into the significant role of social media marketing in the modern marketplace.

LEADERSHIP POWER BASES INFLUENCE ON QUALITY OF WORK LIFE AMONG EMPLOYEES AT A SELECTED RETAIL OUTLET IN GAUTENG PROVINCE

E.M. Maphanga

Vaal University of Technology, Vanderbijlpark, South Africa

B.A. Mokoena

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

Retailing refers to the activities involved in selling goods or services to the final consumer for personal use as opposed to business purposes. It is a socio-economic system that gets people together to interchange goods and services for a small payment, which matches the final consumers' needs. In South Africa, the industry has grown by a yearly average of 3 percent in the past eight years and Gauteng, as a province, contributed 26.5 percent to this growth. Therefore, the retail industry has been growing at a very slow rate. The primary objective of the study was to examine the influence of selected leadership power bases on quality of work life (QWL) among employees at a selected retail outlet in Gauteng province. A quantitative research approach was followed in this study and a random probability sampling method was adopted. A structured questionnaire, divided into four sections, was utilised to survey 300 (both male and female) employees from three branches of the selected retail outlet. The pilot study preceded the main survey and the internal consistency reliability was ascertained. Of the 300 questionnaires distributed to the participants, a total of 285 responses were usable for data analysis (response rate of 95 percent). The Statistical Package for Social Sciences (SPSS), version 26.0, was used to analyse data into descriptive statistics, reliability and validity analysis, correlations and finally, regression analysis, which was used to test the relationship among the constructs under investigation. The results indicated that coercive power base ($\beta=0.456$) and legitimate power base ($\beta=0.210$) contribute positively to the prediction of QWL, while reward power indicated a negative prediction of QWL ($\beta=-0.044$). Cronbach's alpha values ranged from 0.764 to 0.913, (exceeding the threshold of 0.7), thus suggesting that all the items in the measuring instrument tap into the same underlying constructs. Findings from this research study will assist retailers to increase the QWL levels in their companies by advancing the factors that were identified in this research study. Additionally, these findings may enable retail store managers to comprehensively understand how employees perceive power bases and how these employees' perceptions influence QWL. The implications of the results are addressed as well as the limitations of the study and future research opportunities are further identified.

Keywords: Retailing, coercive power, legitimate power, reward power and quality of work life

1. INTRODUCTION AND BACKGROUND

Retailing is a socio-economic system that gets people together to interchange goods and services for a small cost, which serves people's needs, the final consumers (Rudrabasavaraj 2010). Amit and Kameshvari (2012) refer to retailing as a group of activities whereby products and services

are promoted to ultimate consumers for personal or household consumption. Thus, retailing in this regard refers to the activities involved in selling goods or services to the final consumer for personal use as opposed to business purposes. Indeed Hameli (2018) concludes that retailing consists of all of the undertakings of goods sold to ultimate buyers.

South Africa remains the most developed economy in Sub-Saharan Africa and the retail sector is the second biggest employer in the country (Vather 2008). The retail sector is a labour-intensive industry employing a large number of the workers (Vijayakrishna 2013). The industry has grown by a yearly average of 3 percent in the past eight years; with Gauteng province contributing 26.5 percent to this growth. However, according to Statistics South Africa (2018), it has been tough for the retail industry as even in the most crucial month, December 2018, sales fell by 1.4 percent. The report further shows a low growth of 3.1 percent in 2017 and 1.7 percent in 2016. Therefore, the retail industry has been growing at a very slow rate.

There is, however, a need to note that the nature of the workforce in retail today is generally very different from the workforce of the past decades. Effective and efficient management of employees today, for example, is a significant determinant of success for retailers in firms of any size.

This means that the power base a retail manager wields with regard to leading can have a major impact on employees. Indeed, Robbins and Judge (2013) suggest that leaders need to possess power in order to influence others towards acceptable or needed behaviour. Igbaekemen and Odivwri (2015) describe the exercise of power as a process that helps to explain how different leaders can influence the behaviours and actions of other employees within an organisation. Somoye (2016) refers to power as the probability that one may be in a position to carry out his/her will despite resistance from other employees. Thus, retail managers use power to get the best quality of work in order to maintain the perceived standards of their respective companies.

Employees' quality of work life (QWL), on the other hand, reflects the way employees organise and interpret their impressions in order to give meaning to their environment and, thus, it influences their workplace behaviour significantly (Sharif, Zaidatul, Rashid & Mohd 2013). QWL is positively associated with the work outcomes of employees (Berta, Laporte, Perreira, Ginsburg, Dass, Deber, Baumann, Cranley, Bourgeault, Lum, Gamble, Haroun & Neves 2018). It should also be noted that in recent years, QWL has become a significant tool in attracting well-qualified personnel with experience (Mbui 2014:1) and retaining employees (Sojka 2014:283).

Nanjundewaraswamy and Swamy (2014:3) are of the view that leaders with a substantive leadership power base are able to encourage the participation of subordinates in an effort to improve their productivity.

Against this background, the study examines the influence of coercive power, reward power and legitimate power bases on QWL within a selected retail outlet in South Africa.

2. LITERATURE REVIEW

The literature review is focused on the selected leadership power bases that may have the tendency to enhance QWL among retail outlets employees in Gauteng province.

2.1 Coercive power base

Coercive power is predicated entirely upon fear and takes place when someone who is in an authority position threatens subordinates with different reprimands if certain duties are not completed in time and appropriately (Singh 2009:). Banerjee (2009:8) defines coercive power as the power based on subordinates' perception that a superior has the potential to punish them for not conforming to set requirements. In concert, Anthony, Ree and Carretta (2015:5) also view coercive power as subordinates' perception that a superior has the ability to punish them if they fail to conform to the superior's influence. Therefore, coercive power is conveyed through fear of being punished, demoted, not being recognised or even losing one's job (Chakrabarti 2014:5). For this reason, employees fear punishment and choose to either comply or leave.

Megheirkouni (2018:7) concludes that a coercive power base used by leaders has either a negative or positive impact on employees' intention to stay. On the other hand, Robbins and Judge (2013:240) argue that managers believe that their employees naturally dislike work and, therefore, must be directed or even coerced into performing. Based on these assertions, the system of punishments and rewards is solely dependent upon the followers. The following hypothesis is then set for the study:

H1: Coercive power base significantly influences employees' quality of work life

2.2 Reward power base

Somoye (2016) defines reward power as the power to reward subordinates and give incentives for carrying out certain operational duties and orders given by a superior body. Examples of reward power include, but are not limited to promotions, bonuses, salary increments, time off from work and public recognition. Thus, people comply because it yields positive benefits for them (Robbins & Judge 2013). This implies a promise to increase an employee's benefits, which benefits can only be provided by the person in the position of leadership force the employee to comply (Omisore & Nweke 2014). Hassard and Cox (2015) point out that an imbalance in the relationship between the effort exerted and rewards received has a direct bearing towards employees perceptions on QWL. Furthermore, Megheirkouni (2018) established that reward power based behaviour of leaders has a strong effect on an employee's QWL. Based on the preceding argument, the following hypothesis is proposed:

H2: Reward power base significantly influences employees' quality of work life

2.3 Legitimate power base

Legitimate power is the power that derives from holding a high position of power at work (Somoye 2016). This type of power is recognised and accepted by subordinates as being in agreement with the laid down rules and regulations that are considered legitimate by both parties (Bernard & Umar 2014). Igbaekemen and Odivwri (2015) expressed that legitimate power is based on the roles leaders play in the organisation and on the nature of the leaders' personal relationship with other employees. Furthermore, Somoye (2016) portrays legitimate power as the right way of directing employees and getting them to do things they would not normally want to do during the course of working hours. Based on the foregoing arguments, the following hypothesis is proposed:

H3: Legitimate power base significantly influences quality of work life

2.4 Quality of work life (QWL)

Nazir, Qureshi and Shafaat (2011) define QWL as a combination of strategies, measures and ambience related to the workplace that enhance employee satisfaction by improving work conditions for employees. Kanten and Sadullah (2012:361) further describe QWL as a consideration for employees' exigency and desires with regards to working conditions, career development opportunities, remuneration, work-family role balance, leadership power base and social interactions. Similarly, Shankar (2014:901) observes QWL as the degree to which employees are able to satisfy their important personal needs while employed by the organisation. Furthermore, Acharya and Siddiq (2017:584-585) concede that the purpose of QWL is that of attaining greater levels of job involvement and motivating employees by improving the attractiveness of the work itself rather than improving only the terms and conditions of work.

In essence, QWL shows a balance both in work and personal life, which also ensures organisational productivity, employee job satisfaction and intention to stay with the same organisation for longer (Mohammad 2012:1). Therefore, the QWL of an individual is inclined by the direct experiences of work and by the direct and indirect dynamics that affect the experience.

3. METHODOLOGY

3.1 Research design

This study adopted a combination of descriptive and causal research design. The descriptive research design was applied in analysing the demographic profile of respondents, while causal research was utilised in addressing the predictive relationships between the various research constructs. A cross-sectional research design was employed since data was gathered only once from one sample group of respondents to understand and describe the broad characteristics of those selected leadership power bases that influence QWL among employees within a selected retail outlet.

3.2 Sampling method

A convenience (non-probability) sampling method was used to draw the sample as it was duly practical and effective under the COVID-19 related lockdown restrictions in 2020. For the determination of the sample size, the study was guided by Pallant (2016) recommendation of sample sizes of 250-400 for multivariate analysis such as regression analysis.

3.3 Research instrument

A questionnaire was preferred as a measuring tool as it is simpler to administer and eases the variability in the outcomes that may be instigated by dissimilarities in other types of interviews (Malhotra 2010:225). The questionnaire was self-administered to attain relevant data from the respondents and comprised four sections. Demographic and general questions included age group, gender, ethnicity, level of study, etc. The questionnaire further included adapted scales from previous studies for all the constructs measured. The leadership power bases scales (with a reported reliability of 0.87) were adapted from the revised Rahim Leader Power Inventory (1988) while the QWL scale (with a reported reliability of 0.87) was derived from the scale developed by Chinomona and Dhurup (2014) Furthermore, the sections on the study constructs were varied,

using a five point Likert and semantical differential scales to address issues of common method bias in scale construction.

3.4 Data collection

In this study, data were collected by means of a survey method whereby a structured questionnaire was used, since it is cost effective, easy to administer and has a high response rate compared to other forms of data collection instruments (Malhotra 2010:225). Data were collected from three different stores of the same retail outlet company with the assistance of three trained fieldworkers in order to avoid unclear variances on the data and to mitigate against possible low response rates.

3.5 Statistical analysis

The data were analysed using the Statistical Package for Social Sciences (SPSS), version 26.0. Descriptive analysis was utilised to report on the profile of the retail employees. Correlation and regression analysis were applied to examine associations and predictive relationships among the study constructs for hypothesis testing.

4. RESULTS

4.1 Sample composition

A majority of the respondents were females (66%; n=223) as compared to their male counterparts (34%; n=113). The largest group of respondents were between 21 to 30 years of age (n=223; 66.4%), had a matric qualification (n=241; 71.7%) and indicated a work experience of between 7 to 10 years of service in the retail environment outlet (n=193; 57.4%).

4.2 Correlation analysis

The purpose of this analysis is to discover whether two or more variables are in some way associated with one another (Leedy & Ormond 2021). The study utilised Pearson's correlations analysis as reported in Table 1.

Table 1: Inter-construct correlations, descriptive statistics and reliabilities

| Construct | CP | RP | LP | QWL | MEANS | SD | Cronbach alpha |
|-----------|--------|--------|--------|------|-------|-------|----------------|
| CP | 1.00 | | | | 3.71 | 1.303 | .808 |
| RP | .242** | 1.00 | | | 3.64 | 1.324 | .847 |
| LP | .464** | .512** | 1.00 | | 3.75 | 1.282 | .764 |
| QWL | .542** | .173* | .756** | 1.00 | 3.32 | 1.363 | .863 |

CP= Coercive power base, RP= Reward power base, LP= Legitimate power base, QWL= Quality of work life. **Correlation is significant at the 0.05 level (2-tailed).

An analysis of the correlation matrix indicates significant positive associations between the research constructs.

4.3 Reliability and validity

The Cronbach's coefficient alpha was used to assess the internal consistency of each construct employed in the study and the accuracy of the questionnaire. Table 1 reports that all alpha values ranged from 0.764 to 0.863, thus exceeding the recommended threshold of 0.7, which according to Pallant (2010:97) is regarded as satisfactory. Face and content validities were tested through a

review of the questionnaire by subject experts in the human resources field. A pilot study was undertaken to assess construct validity. All scales attained average item correlations above the recommended threshold of 0.3 and Cronbach alpha values were above 0.7 as the minimum threshold recommended (Leedy & Ormrod (2010:92) ensuring convergent validity. The hypothesised relationships between variables were tested using regression analysis to provide evidence of predictive validity (Malhotra *et al.*, 2017).

4.4 Regression analysis

Regression analysis is a procedure for analysing associate relationships between a metric-dependent variable and one or more independent variables (Malhotra, Nunan & Birks, 2017). Prior to the computation of the regression model it was necessary to assess whether the data set posed any multicollinearity problems. Multi-collinearity was assessed by inspecting the tolerance value (Tol) (>0.1) and the variance inflation factor (VIF) (<10) for each construct. As shown in Table 2, all the three independent variables had VIF values of <10 and tolerance value of >0.10, thus dispelling any multicollinearity threat (Malhotra, 2010). Regression analysis was then performed and the results are recorded in Table 2. The enter method of regression was chosen as each independent variable is evaluated in terms of its predictive power, over and above that offered by all the other independent variables (Pallant, 2010). In the regression model, (Table 2) QWL was entered as the dependant variable while the three predictors (CP, RP and LP) were entered as independent variables.

Table 2: Regression model

| DEPENDENT VARIABLE: QWL | Standardised beta | T | Sig | Collinearity statistics | |
|------------------------------|----------------------|-------|------|-------------------------|-------|
| | | | | Tol. | VIF |
| Independent variables | | | | | |
| Coercive power (H1) | .456 | 8.886 | .000 | .770 | 1.229 |
| Reward power (H2) | -.044 | -.827 | .409 | .710 | 1.409 |
| Legitimate power (H3) | .210 | 3.556 | .000 | .582 | 1.720 |

R=0.571 R²=0.326 Adjusted R²=0.320 F change 53.588 **sig at <0.05. Tol.= Tolerance value, VIF= Variance inflation

Overall, the three predictor variables (CP, RP and LP) accounted for 32% (Adjusted R² = 0.320) of the variance in QWL. These results indicate that QWL is attributed to the combined effect of the three predictors.

5. DISCUSSION OF RESULTS

5.1 Descriptive statistics

With respect to descriptive statistics, Table 1 indicates that all the mean scores returned for all the constructs were all above the score of three on the Likert scale (>3 – <5) suggesting that the respondents recognise the significance of these constructs within the retail outlet. The standard deviations were less than two, therefore, indicating that the mean values are correct reflection of the majority average perceptions.

5.2 Correlations

The results of the correlation analysis showed a significant strong positive association between coercive power and QWL (r=0.542; p<0.05). These results suggest that an increase in coercive power may trigger an improvement in QWL among employees in a retail setting. There was a

significant yet weak positive association between reward power and QWL ($r=0.173$; $p<0.05$). This result implies that an increase in reward power among employees within a retail outlet may slightly improve their QWL. Further analysis of the correlation matrix indicates a significant strong positive association between legitimate power and QWL ($r=0.756$; $p<0.05$). This indicates that as legitimate power increases among employees, they will experience a high level of QWL.

5.3 Regression

The first hypothesis (H1) states that a significant relationship exists between coercive power and QWL among employees in a selected retail outlet in South Africa. The regression analysis results ($\beta=0.456$, $t\text{-value}=8.886$, $p>0.000$) show that coercive power is a significant predictor of QWL. These results confirm the findings of previous studies conducted by Blanchard (2016:9) which demonstrated that coercive power positively shape employee QWL. Thus, H1 is supported.

The second hypothesis (H2) states that there exists a significant relationship between reward power and QWL among employees in a selected retail outlet in South Africa. The regression analysis results shows that reward power has a negative insignificant association with QWL ($\beta=-0.044$, $t\text{-value}=-0.827$, $p>0.409$). This finding refutes studies of Omisore and Nweke (2014) who revealed that reward power significantly influences employees QWL. Thus, H2 is rejected.

The third hypothesis (H3) states that there is a significant relationship between legitimate power and QWL among employees in a selected retail outlet in South Africa. The regression analysis results ($\beta=0.210$, $t\text{-value}=3.556$, $p<0.000$) provide empirical evidence to support the H3. The results of this study are in line with previous studies undertaken by Tost, Plunkett, Gino and Larrick (2018), which indicated that legitimate power plays a vital role in behavioural and attitudinal compliance.

6. LIMITATIONS AND IMPLICATIONS FOR FURTHER RESEARCH

The results are limited to employees from one retail outlet in South Africa. Therefore, these results cannot be generalised across the categories of the retail environment at a national level. The results must therefore be viewed with caution. A broader and more geographically diverse group of participants can be considered in future related studies. This would enlarge the research sample to include a much more representative section of the population. Only three leadership powerbases (coercive power, reward power and legitimate power) were part of the study. Additionally, other leadership powerbase variables such as expert power, referent power and information power could be avenues for further research. Furthermore, the study relied upon self-reported data to test the proposed conceptual framework. There is a possibility that some respondents may have inflated or understated the extent of their assessment of the study constructs. Lastly, a single method of data collection (quantitative approach) was used. It would be advantageous that future research consider using both quantitative and qualitative research approaches to complement each other.

7. CONCLUSION

Overall, the study contributes to the current literature by focusing on leader power base effect on QWL among employees within the retail industry in South Africa, offers suggestions to improve QWL among employees and opens up avenues for further research in this field.

ABSTRACT

Employability skills channel graduates into desired career choices. This paper focuses on the nature of interfaces between Technical and Vocational Education and Training (TVET) stakeholders (industry, graduates, lecturers) in engineering. A qualitative case study approach undergirds this study. The research study was done in the Kwazulu-Natal Province at a TVET college and three local companies. Data were generated from open-ended questionnaires and semi-structured interviews guided by policy documents for National Accredited Technical Education (NATED) and National Certificate (Vocational) (NCV) curricula. The study's conceptual framework drew on Singh-Pillay (2010)'s notion of interface and the Employability Skills Framework by Curtis (2004). Data analysis was done through document and content analysis and thematic methods. The results for sustainable employability skills were juxtaposed to establish the existence of interfaces. This study contributes to knowledge on interfaces between industry, TVET graduates and lecturers and economic and human development. Further, the study reveals the mismatch between skills outlined by policy and syllabi versus skills acquired by TVET graduates and industry-required skills.

Keywords: Interface, stakeholders, employability skills, engineering industry, skills, TVET policy.

INTRODUCTION

The Technical and Vocational Education and Training (TVET) sector aims to prepare graduates to take up different occupations in the workplace. From the dawn of democracy, the South African TVET sector has undergone major transformations, as indicated in the White Paper for Post School Education and Training (PSET) (Department of Higher Education and Training, 2013), that TVET students could learn skills which create employment opportunities in industry. TVET institutions are regarded as the conduits for skills development that provide individual professional development opportunities (Mesuwini et al., 2020). A distinctive feature of TVET is outlined by Zelloth (2014), who describes TVET as a learning process with a practice-oriented or work-integrated learning component. Through this work-based learning, graduates are expected to possess a particular industry-specific skillset based on the fundamental theoretical principles that support professional competence development.

The study explores the interfaces between the stakeholders' skills set and TVET graduates' employability skills. Often, the TVET sector has been under scrutiny by various stakeholders for

not realising their primary responsibilities and being responsive to industry needs (Mesuwini & Bomani, 2021). The lack of essential workplace skills constrains the economic growth of any country and its human capital development. In this regard, Sweden and Germany are regarded as countries with companies that are highly involved in TVET delivery and governance (Zelloth, 2014), while to a lesser extent, Canada, Australia and England integrate industry partners (Rauner & Wittig, 2013). South Africa's government has enormously invested in the TVET sector and allocated R10.7 billion in 2018 (Viljoen, 2020) to cater for artisan development, infrastructure development, and student support grants. In this view, the Department of Higher Education and Training (DHET) launched its Decade of the Artisan programme (2014-2024), which aimed to produce 30 000 artisans yearly (Skillsportal, 2014). Through artisan knowledge and skills, TVET graduates are provided with industry-specific skills to match the trade skills requirements.

Singh-Pillay (2010) explains that an interface arises from points of convergence and divergence among different stakeholders' requirements concerning skills development. This understanding forms the basis of discussion in this study. The notion of an interface is construed as a point of contact (convergence) or a point of deviation (divergence) among stakeholders concerning the phenomenon under study (Mesuwini, 2015). The interfaces that emerge are discussed first regarding sustainable employability skills. Secondly, a cross-interface analysis is tabled to reveal the nature of these interfaces in terms of sustainable employability skills. The two policies, NC(V) and NATED, have different methods of delivering content. The NATED curriculum is 100% theoretical, while NC(V) is 40% theory and 60% practice. NC(V), on the one hand, plays a positive role where practical skills are foregrounded. NATED, on the other hand, serves as a background for entry into off-campus training programmes as required by employers.

Purpose

This study explores the nature of interfaces between TVET stakeholders (industry, graduates, lecturers) and highlights if there is a mismatch between the skills outlined by policy and syllabi, skills.

Justification of the Study

There appears to be limited literature on the nature of interfaces between TVET stakeholders (industry, graduates, lecturers). It is not clear whether their voices have been silent or not heard. The White Paper on PSET (Department of Higher Education and Training, 2013, p. 11) states, "*Colleges should be rooted in their communities, serving their communities and regional and national needs*". The TVET should predominantly deliver education and training to nearby communities and develop skills for local industry. There should be a symbiosis among stakeholders regarding employability skills that TVET graduates should acquire to be industry-ready. In this view, the TVET syllabi, industry, and lecturers need to have a common ground on the employability skills that TVET graduates should gain during training. The above explains the objective of this study which aims to explore the nature of interfaces between TVET stakeholders' skillsets.

Contribution to Knowledge

There are three suggested success components for research: contribution, contribution, and contribution (Te'eni et al., 2015). This study is considered a valid knowledge contribution when

little is known about the phenomenon being studied. This exploratory study provides insight into the convergence /divergence of interfaces between TVET stakeholders regarding the required employability skills of their learners.

LITERATURE REVIEW

NATED in South Africa covers the Engineering trimester and Business semester courses. This paper focuses on Engineering NATED and NCV courses. Engineering NATED trimester is generally described as a 10-week course, while NCV is a year course (Mesuwini, 2015). The literature concerning the disjuncture between skills required for work and skills acquired by graduates is brought to the fore. There appears to be some tension between skills required, skills acquired and human and economic development. At the intersection of these skills lies the TVET college sector. The TVET sector may ease this tension by developing these much-needed industry skills, contributing to human resources/capital and economic development. The required skills may be a way of training TVET students for work-related fields and effective participation in the workplace; an aspect of lifelong learning and readiness for responsible citizenship; an instrument for supporting environmentally sound, sustainable development and a way of alleviating poverty (United Nations Educational Scientific and Cultural Organization, 2015). TVET has the transformative capacity that promises its graduates the right to employment (Mesuwini, 2015). Employability skills refer to the ability of an individual to gain employment appropriate to his educational standard (Singh & Singh, 2019). Employability may depend on how these skills, knowledge and attitudes are used, deployed and presented within a particular work context. Various studies investigated employability skills required by the industry.

Nisha and Rajasekaran (2018) highlight the significance of employability skills by exploring the different kinds of skills perceived by employers. The employability skills highlighted by employers included communication skills, teamwork skills, problem-solving skills, leadership skills, interpersonal skills, entrepreneurial skills, and analytical skills. Communication is the unity of the difference between utterance, information, and understanding (Baraldi & Corsi, 2017). The employability skills shaped students' careers and emphasised how they can assist them in achieving greater career heights. The study suggests essential employability skills needed in the workplace.

Singh and Singh (2019) investigated employability skill sets expected from engineering graduates. Responses were sourced from the viewpoint of representatives of private engineering institutions and human resource managers of companies. The identified skills gap suggests the important measures private institutions take to attain employability skills. The study attempted to inculcate these skills in students and how it impacts national growth.

Mittal and Raghuvaran (2021) revealed that entrepreneurship skills built competencies in students and increased their capabilities for putting knowledge into practice. Therefore, students with entrepreneurial skills were said to have better employability skills and a workplace advantage. In another study, Laguna-Sánchez et al. (2020) analysed the attainment of skills acquired in a training programme to develop entrepreneurial and employability competencies. The results suggest acquiring a higher level of proficiency in entrepreneurial skills and gaining transversal competencies. It remains to be seen what interface exists between stakeholders' skill sets.

The concept of an interface is construed as a meeting point (convergence) or a point of deviation (divergence) among stakeholders concerning the nature of interfaces explored. I first discuss the interfaces that emerged regarding sustainable employability skills. Second, a cross-interface analysis is presented to highlight the nature of these interfaces in terms of sustainable employability skills.

CONCEPTUAL FRAMEWORK

The study's conceptual framework drew on Singh Pillay's notion of interface and Employability Skills Framework (ESF) by Curtis (2004). The framework has its roots in the Mayer key competencies. Key competencies are essential for effective participation in emerging work patterns and organisations (Curtis, 2004). Australian Education Council: Mayer Committee (1992) describes competencies as essential for effective participation in emerging work patterns. The Australian Education Council: Mayer Committee (1992, p. 12) proposed the following characteristics for generic skills: *“be essential to prepare for employment; be generic to the kinds of work emerging in the range of industry occupations; equip individuals to participate effectively in various social settings; involve knowledge and skill application; be amenable to credible assessment”*. These characteristics guided the formation of ESF by Curtis. They focus on the capacity to apply knowledge and skills in integrated work situations. The eight employability skills are: Communication, teamwork, problem-solving, initiative and enterprise, planning and organising, self-management and learning skills. Employability skills are important because they bring significant changes to the economy and how companies operate, requiring employees to possess these skills. Jobs in this era require flexibility, initiative and the ability to multitask. The ESF incorporates the Mayer key competencies within the major skills.

The Key Competencies are essential for effective participation in TVET education in general. Globally, key competencies are core skills in the United Kingdom, essential skills and employability skills in Canada, and Secretary's Commission on Achieving Necessary Skills (SCANS) in America. The following table summarises the generic skills referenced in the discussion.

Table 1: Generic Skills

| Generic skills | Workplace Competencies |
|-------------------------|---|
| SCANS | Basic skills (literacy, numeracy, communication), Thinking skills (decision-making, problem-solving), Personal qualities (responsibility, self-esteem, integrity). |
| Core skills | Communication, problem-solving, personal skills, numeracy, information technology, language competence |
| Key skills | Communication, information technology, working with others, improving learning and performance, and problem-solving. |
| Essential skills | communication (oral, reading and writing text), document use, numeracy, thinking skills (problem-solving, decision-making, planning and organising tasks, significant use of memory, and finding relevant information), working with others, computer use, continuous learning. |

| Generic skills | Workplace Competencies |
|-----------------------------|--|
| Employability skills | Academic skills (Communicate, employability, learning skills) Personal management skills (Personal skills, positive attitudes and behaviours to get and keep a job). Adaptability, responsibility, working safely, Teamwork skills (working with others, skills to achieve the best results). |
| Key competencies | Communicating ideas and information Using mathematical ideas and techniques Working with others and in teams Problem-solving problems Planning and organising activities Collecting, analysing and organising information Using technology. |

Adapted from Curtis (2004).

Notes:The workplace competencies listed above are shown against each generic skill described globally. Kearns (2001) agrees on finding acceptable terminology for all stakeholders—TVET, higher education, employers, students, and communities which recognise that the new agenda of generic skills for the 21st century is about employability skills.

Singh Pillay’s Notion of Interface

Interfaces arise out of points of convergence and divergence (Singh-Pillay, 2010) between elements or people’s views. It is this understanding that is applied in this study. The concept of an interface is construed as a meeting point (convergence) or a point of deviation (divergence) between sustainable employability skills acquired (via the curriculum) and required (by graduates, employers, and lecturers). The sustainable development approach emphasises the purpose of TVET as the provision of skills to support economic, social and environmental sustainability. The sustainable development approach has broadened the concept of employability to include lifelong learning, sustainable economies in the context of the information age and the knowledge economy, education for all, and education for human security. The role of TVET is the preparation of learners for sustainable livelihoods (Tikly, 2013). Competencies in economic literacy, sustainable consumption and managing small enterprises are emphasised in relation to the economic aspects while using resources wisely and minimising waste and pollution are considered central to ensuring environmental sustainability (Maclean & Pavlova, 2013).

The notion of interface was used to look for congruence (convergences) or divergences (non-congruence) regarding sustainable employability skills acquired and required. The factors that enable or impinge the interfaces will be used to explain the nature of the interface.

The relationships at the interface are indicated in Figure 1 below.

Figure 1: Interface among Stakeholders

Notes: Figure 1 shows lecturers, curriculum, employers and graduates meeting at the interface. The interface describes the common areas shared by all stakeholders.

Employability skills development requires involvement from employers, students, TVET, and other stakeholders to achieve skills development (Maclean & Pavlova, 2013). The role of TVET is the preparation of learners for sustainable livelihoods (Tikly, 2013).

METHODOLOGY

A qualitative research approach was employed in this study. Kankam (2020) maintains that using a qualitative approach seeks to establish the meaning of a phenomenon from the participants' perspective. A case study approach from KwaZulu-Natal province, South Africa, was used to explore the skills sets required by TVET graduates from the perspective of policy (NCV and NATED), lecturers (6), and TVET graduates (3) and employers (3). A case study approach explores a phenomenon to understand it in detail. Chowdhury and Shil (2021) maintain that a case study is an empirical inquiry approach to investigating a phenomenon within its real-life context. The study used convenience and purposive sampling to select participants. Convenience sampling was selected based on affordability, accessibility, and proximity of the data sources. Purposive sampling allowed handpicking potential participants to be included in the sample based on their judgement of the typicality or possession of the particular characteristics sought (Muzata, 2020). Purposive sampling identifies the relevant participants with the right information (Campbell et al., 2020).

The selected participants were graduates in the researcher's proximity and had completed their studies. Employers were host companies that offered training to graduates during industry exposure. Reliability was maintained by ensuring that adequate resources to generate data were available and that the steps were consistent throughout the process. Validity in this study was addressed through honesty and ensuring that rich data were gathered without bias.

This study gathered qualitative data using an open-ended questionnaire, semi-structured interview and document analysis. The different methods of generating data allow for data triangulation by cross-checking or juxtaposing data from different sources (Mesuwini, 2015). Triangulation increases credibility and checks dependability by obtaining information from different sources to form reliable themes in a study. These instruments were suitable for generating qualitative data and answering the research questions. An open-ended questionnaire was used for TVET lecturers, employers and graduates because it did not limit responses. Li et al. (2021) maintain that open-ended questionnaires permit creativity, self-expression and richness of detail. The questionnaires

were piloted using a group of TVET engineering lecturers to check the clarity of the questions and eliminate any possible ambiguities. Some questions were reworded for clarity. A semi-structured interview allowed for probing of participants’ responses. However, Zoch (2021) cautions that interviewer bias is greatest in a face-to-face interview. This was avoided by letting participants give their responses without intercepting them. Galetta (2013) emphasises discipline on the researcher’s side, allowing space to develop the narrative and holding back some questions until the participant has covered sufficient ground in the responses. Anonymity and confidentiality of participants were maintained strictly, consistent with Cohen et al. (2017), who emphasise that the confidentiality and anonymity of participants' information should be sustained. Formal permission from various gatekeepers was obtained to conduct research at each stage.

DATA ANALYSIS

The study used Jansen and Reddy (1994) tool to analyse the NC(V) and NATED TVET documents. Donthu et al. (2021) define document analysis as a strict and systematic set of processes for rigorous data verification and analysis. Singh-Pillay's notion of interface was used to identify points of convergences or divergences in terms of sustainable employability skills. The nature of the interface was ascertained by exploring the factors that contributed to refractions at the points of convergences and divergences. As indicated by validity and reliability, research rigour was maintained by engaging in member checking, triangulation, and retaining thick descriptions. Member checking ensured the credibility and validity of the research. Thick descriptions provided detailed narratives and interpretations of situations observed and experienced by the researcher (France, 2022). The process involved taking back the transcripts to participants and asking them to check the accuracy of the recorded data. The researcher's position was defined and attempted to address the bias inherent in interpreting qualitative data, including member checking, which ensured that the key issues had been interpreted correctly (Walton, 2020).

RESULTS AND DISCUSSION

Analysis of the Skills set for Sustainable Employability Interface

Data from curriculum or policy documents, lecturers, graduates, and employers were compared to determine whether an interface existed in the skills set needed for the employability of engineering graduates. The points of convergences to capture existing interfaces were foregrounded to identify current interactions in terms of sustainable employability skills. Table 2 represents the existence of interfaces among stakeholders.

Table 2: Interfaces among stakeholders

| Interfaces | |
|------------|---|
| A | Policy-Employer-Lecturer-Graduate Interface w.r.t. mechanical, electrical and civil skills. |
| B | Policy-Lecturer-Graduate Interface w.r.t. safety skills. |
| C | Policy-Lecturer-Employer Interface w.r.t. communication, problem solving and computer skills. |
| D | Policy-Employer Interface; w.r.t. quality work and time management. |
| E | Lecturer-Graduate Interface; w.r.t. machine operations; supervision of workers; correct tool handling and background knowledge. |
| F | Policy-Lecturer Interface w.r.t. on analytical skills, creativity and problem-solving skills. |

Table 2 above demonstrates that certain interfaces involve 2 to 4 stakeholders. The interfaces point to the areas of convergences (agreements) among the stakeholders regarding skills needed for

sustainable employability. Table 3 shows the interfaces on the needed skills for sustainable employability as perceived by different stakeholders.

Table 3: Interfaces on Skills Needed for Sustainable Employability

| Stakeholders | Interface among stakeholders |
|--|--|
| The Policy-Employer-Lecturer-Graduate interface | The interface involves all four stakeholders. These four stakeholders concur on the skills set for sustainable employability required by the TVET graduate in the following trades: mechanical, electrical and civil skills. Mechanical: Safety skills, Tool handling, Engineering Drawing and interpretation. Electrical: Safety skills, Hand tool skills, Reading Electrical Drawing. Civil: Safety skills, handling skills, Reading and Drawing plans. |
| Lecturer-Graduate-Employer Interface | The interface highlights the need for job-specific skills. Three of the four stakeholders agree that the essential skills for sustainable employability are listed below: Mechanical: Automotive Repair & Maintenance, Welding, Boiler making, Fabrication, Machining, Reading Drawings. Civil: Carpentry & Roof Work, Plumbing, Bricklaying, Plastering, Reading drawings. Electrical: House wiring, tubing, reading drawings, fault finding, communication skills, report writing and computer literacy. Drawings are common in all disciplines, while the other skills are discipline-specific. |
| The Policy-Lecturer-Employer Interface | The Policy-Lecturer-Employer interface reflected convergences in communication, problem-solving and computer skills. It implies that there were no common skills identified among these three stakeholders. If skills were common to these three, they were also common to the graduates. |
| Lecturer-Graduate Interface | The lecturers and graduates consider the following skills vital for sustainable employability: machine operations, supervision, correct tool handling and background knowledge. |
| The Policy-Lecturer-Interface | The interface was founded on analytical skills, creativity and problem-solving skills. |

Nature of Interface of Skills Set Required for Sustainable Employability

In describing the nature of inference, the reasons offered by the stakeholders were examined from the interviews to obtain the contextual factors that shape these interfaces. The Policy-Lecturer-Employer interface matches the key workplace competencies postulated by Curtis (2004).

Underqualified and inexperienced lecturers

Employers maintain that inexperienced and unqualified lecturers impeded skills development in TVET graduates, as shown in the excerpt below:

It seems many lecturers have not been in industry at all. Therefore, they lack the know-how and understanding of vital concepts and cannot teach different issues. As a result, many graduates have gaps in their knowledge and cannot perform the jobs they are trained for (Employer 1).

Lecturers seem unhappy about their lack of exposure to and experience of industry requirements, as reflected in the excerpt below:

Lecturers are teaching because they cannot fit into industry. They do not have the experience to train individuals who can compete effectively on the job market. These lecturers are a liability to the system. Qualified and experienced lecturers leave teaching to the industry for better offers. More surprisingly, no lecturers engage in technology degrees for staff development (Lecturer 3).

The above finding concurs with Mutereko and Wedekind (2017), who posits that most lecturers with education qualifications have general qualifications or those related to school teaching rather than qualifications designed for college lecturers. Likewise, the Department of Higher Education and Training (2022) argues that the greatest challenge in improving and expanding TVET colleges is the capacity of lecturers, particularly their subject-matter expertise. Lecturers drive curriculum delivery, meaning they need to be knowledgeable in their respective trades and offer successful training. Learning from Germany, graduates with a Bachelor's degree go through industry exposure to improve their practical skills and employment opportunities (Maclean & Pavlova, 2013). In this way, the lecturers would obtain generic skills to equip students with workplace competencies.

Unprepared students and strikes for NSFAS

Both lecturers and graduates mentioned students' strikes as hampering the acquisition of the skills set required by graduates. Students who are not ready to learn allegedly incite violence and anarchy because they have nothing to lose. Curtis (2004) highlighted personal qualities, responsibility, self-esteem and integrity as necessary workplace employability skills. The personal qualities exhibited during strikes do not reflect a submissive attitude and character to authority. Luhmann (1995) states that when there is a disruption or disturbance to the equilibrium of an ecology, agents respond by adapting. It aligns with decisions taken when TVET college management succumbs to students' demands to maintain harmony in the 'ecosystem'. Graduate 4 said:

The students' strike for NSFAS money is disturbing learning almost every term.

Lecturer 5 blamed the colleges on "weak recruitment criteria which take students with poor passes". Many factors result in colleges breaking their enrolment policy to either fill class groups or satisfy student leadership demands. The researcher observed such a strike at the college, which resulted in cancelling all full-time NATED trimester examinations. A lack of preparedness to sit for final examinations tended to trigger such strikes. In support of this idea, Lecturer 6 echoed, "The strike for NSFAS by students wastes precious time". Employer 1 commented on the preparedness of students:

Most school leavers want to become millwrights, electricians, boilermakers and fitters, but they do not know about the trades.

The excerpt above shows that a lack of college career guidance prevented students from making appropriate career decisions. Employer 1 further submitted that:

A handful of students seems to know what they want to study. If some students want to become electricians, they will not go to civil because that is where space is available.

The graduates' opinion reflects a poor understanding of the prescripts of trade skills. This is supported in the excerpt below by Employer 2, who said:

It seems those students who come to college want to become electricians, and when it is full, they are redirected to other disciplines. It suggests that students do not know what they want to become.

The excerpt speaks to college enrolment procedures concerning the different courses offered. The primary aim seems to fill available spaces rather than ensure that students enrol for their preferred

career choices. The administrative behaviour highlighted above reveals that the college aims to fulfil enrolment targets at the expense of proper career guidance and career choices. Students were allocated to courses based on available spaces rather than their aptitude or interest, which did not promote the development of the required skills set for sustainable employability. Supporting career guidance the above, Allais and Wedekind (2020, p. 326) posit:

Education has long been part of the problem, turning out graduates who were clueless about how the world works as a physical system or why that knowledge was important to their lives and careers.

Against this backdrop, developing students in their disciplines of interest moulds career-oriented graduates with industry-required employability skills.

Poor Infrastructure and under-resourced workshops

Appropriate resources and qualified lecturers are needed for skills to be fully developed. The resources include computers, workshops with functional equipment, tools and machines, textbooks, visual aids and physical aids for items such as pumps, valves, circuits, panels and trusses (Mesuwini & Thaba-Nkadimene, 2021; Yeap et al., 2021).

In this regard, Graduate 6 stated, "*Group practical tasks prevented hands-on practice for some students*". Freely available resources enhance appropriate skills development without improvising or taking shortcuts. For instance, if the tools have to be shared, this can increase the time to teach a concept. Less time is needed if all students use their tools than they have to share, so teaching time is used more effectively to impart the requisite skills.

A civil engineering Lecturer 6 reiterated:

Infrastructure is necessary for bricklaying so that the weather does not affect projects in progress.

Graduate 3 alluded to the same idea by saying:

More practical tasks are needed at college to meet industry skills and demands.

Baraldi and Corsi (2017) advocate for graduates with skills relevant to current economic needs. The TVET sector should offer short to long-term quality and usable programmes (Maclean & Pavlova, 2013). Besides the lack of resources, Lecturer 2 put forward that:

A lack of the practical component for the NATED programme disadvantaged lecturers' duties as it was very difficult to explain concepts or processes without seeing them in practice.

From the stakeholders' perspective, it is important to provide the resources recommended by policy, to ensure effective teaching and learning, thereby leading to the skills set required by the TVET graduate. A similar study by Legg-Jack (2014) highlights some factors that impede the effective implementation of the curriculum, such as lack of training materials and equipment, a dearth of qualified technical teaching and non-teaching staff, out-of-date and non-functional equipment, lack of staff development and poor management of Technical Education.

The late release of results

The researcher with fifteen years of experience in the TVET sector has noted that examination results are often released a week or two into the following trimester. Since the NATED programme is scheduled for only ten weeks, losing two weeks each trimester compromises the outcome. Registration for current (pipeline) students may not occur until the release of previous results, leading to further delays. Such unproductive use of tuition time leaves an average of eight weeks being used fruitfully every trimester. Experience has shown that lecturers are under immense pressure to complete the course, and there is likely no time to understand the skills taught properly. The loss of time significantly affects the time available for lecturing and planning (Mesuwini & Bomani, 2021). It should be addressed so that teaching and learning are allocated adequate time to avoid keeping the lecturers under pressure, playing “catch-up” and ensuring graduates receive the skills set for sustainable employability.

Lecturer-student ratio

Even though the policy document (Department of Higher Education and Training (DHET), 2017) states that the lecturer: student ratio should be 1:30, colleges do not seem to adhere to this ratio. There is a tendency to enrol high numbers of students for NC(V) because of the high subsidies received from the government for these students (Matenda, 2020; Zulu & Mutereko, 2020). At the same time, NATED subsidies are very low. Therefore, colleges tend to enrol the maximum possible NC(V) students to maximise income.

Lecturer 6 said: “*Sometimes the student numbers are too high to manage*”. The high student numbers strain the available resources, negatively impacting the final results. It also affects the mode of delivery, and more teaching time may be required to ensure the understanding of the requisite skills.

Language barrier

The language barrier was observed through the interviews as a reality. Electrical Lecturer 1 responded that the “*Language barrier had negative effects*”. Language barriers contribute to poor productivity, with mistakes or a general lack of trust between employers and employees. In support, Shaik and Makhecha (2019) add that the language barrier results in a lag in response, language misinterpretation, and bad networks in the workplace. Clear communication can avoid all the points noted above. Students and workers were generally unwilling to speak English, and some felt frustrated and intimidated trying to communicate with English-speaking supervisors or co-workers. Core skills highlighted the importance of language competence in a workplace as skills set. Furthermore, values and integrity, personal and interpersonal skills, and a positive attitude to change were intended to be integrated into national vocational qualifications (Curtis, 2004). To ensure understanding, it is important to seek feedback after instructions have been given, either orally or by demonstration, particularly during training to ensure the same message is shared across the student groups.

Political pressure

The introduction of NC(V) followed financial support from the government. All public TVET colleges offer NC(V) programmes in civil, electrical and mechanical fields, and students who meet

the financial requirements get study bursaries (Lawrence, 2016; Mesuwini, 2015). Civil engineering Lecturer 3 showed some displeasure with political pressure and said:

Political pressure forces TVET colleges to succumb to the demands of recruiting undeserving students into the college sector.

As observed during the interviews, the NC(V) programme is still not widely understood by the industries under study. Promotion of the programme is required to ensure that all stakeholders have a common understanding of NC(V). Bordean and Sonea (2018) comment that a successful recruitment process is a critical driver for the sustainable employability of the business. Mesuwini and Bomani (2021) support that college management often budges to student demands without carefully considering the effects. In this context, Luhmann (1995) explains that the social system has its dynamics, and as such, the TVET needs to gradually blend with industry for a common cause.

Policy discrepancies

Department of Education (2006, pp. 5-6) states that NC(V) is meant to cover the skills gap and:

- Equip its learners with knowledge, skills and values necessary for self-fulfilment and meaningful participation in society as citizens.
- Provide access to further learning in the learner's choice of a specific vocational sector.
- Facilitate learners' transition from formal education to the workplace.
- Provide the employers with profiles of learners' capabilities.
- Deepen the foundation laid by General Education and Training.
- Lay a foundation for specialist learning.
- Prepare learners for employment purposes at any level.
- Develop citizens committed to social demands, such as improved productivity, global competitiveness, and social and economic transformation (FET Act 98/1998).

There is a challenge linking TVET and its syllabi to the constantly evolving industry needs. In this instance, creating partnerships between TVET, industry and other stakeholders is inevitable to ensure synergy between skills offered in the TVET sector and industry expectations.

CONCLUSION

The factors that impacted teaching and learning, such as political pressure, poor infrastructure and under-resourced workshops, were explored and highlighted. Political pressure led to the enrolment of students who focused on getting NSFAS funding instead of studying. Policy differences showed that NC(V) provided vocational skills and access to further learning in a specific vocational sector and equipped students with the knowledge, skills and values needed for self-fulfilment and significant social participation as South African citizens. NC(V) was portrayed as a course offering practical industry skills compared to NATED, which was recorded as totally theory-based. Further studies could focus on a possible increase of time from the NATED trimester to seek ways to eliminate the challenges of running the 10-week course. Further, the NC(V) programme, which is marred by poor attendance, could also be investigated, possibly reducing the study period to six months. Effective career guidance was lacking during enrolment, forcing students into wrong subject choices, which could be corrected by creating strict recruitment criteria across TVET

colleges. Communication, teamwork, problem-solving and computer skills were highlighted as vital for employability skills. These perspectives can inform current policy debates.

HINDRANCES ON POLICE OFFICERS TO COMBAT MOB-JUSTICE: GQEBERHA, SOUTH AFRICA

A. Loqani

University of Fort Hare, Alice Town, South Africa

T.O. Magadze

University of Fort Hare, Alice Town, South Africa,

ABSTRACT

In South Africa, mob-justice is treated as a pandemic. Even though the Constitution Act 108 of 1996, section 12(1) (c) mandates police officers to safeguard the inhabitants of this country, police officers continue to struggle to address the occurrence or reoccurrence of mob-justice. This paper attempts to address challenges faced by police in combating mob justice in Port Elizabeth, currently known as Gqeberha. The point of this focus is holistic understanding of bottlenecks that lead to increased incidences of mob justice in South Africa. Qualitative research methodology with a sample size of 48 participants was used, and data was analyzed through thematic analysis. Findings revealed that, lack of resources, lack of community involvement, police corruption and ineffectiveness of the Judicial System to deal with reported cases are some of the worst factors that contribute to increased incidences of mob justice.

Keywords: Mob justice, hindrances, communities, police officers.

INTRODUCTION AND BACKGROUND

Mob justice incidences have been escalating throughout the world. In South Africa, it has become a critical problem for the public and the government, particularly the South African Police Service (SAPS) as it reflects badly on the country's security efficiency. Furthermore, the Criminal Justice Systems (CJS) recognized as a significant institution in this country is negatively affected by this phenomenon as citizens depend on them for safety and security. Undoubtedly, policing is fundamental in all societies and expected to ensure maintenance of order, safety and social interaction. Rising population rates, urbanization and high unemployment rates translate to more demand for police to ensure security for citizens (Ojo, 2014). Malik (2016) holds the same viewpoint, claiming that urbanization and rising unemployment encourage crime since crime rate is higher in large cities and urbanized areas.

However, the inability of the police to maintain order and safety in most areas encourage community members to resort to mob justice. Gross (2016) argues that mob justice in South Africa is not completely due to dissatisfied and disappointed expectations on South Africa's transition to democracy after 1994; rather, mob justice seems to be a phenomenon that originated through a surge in crime and failure of the police to respond to criminal cases. As a result of the high rate of crime, lower-income citizens feel relatively insecure compared to wealthier neighbours who have greater access to private and public security. Unlike wealthier neighbourhoods, lower-income citizens depend on the police for protection; due to police invisibility in their communities, they perceive mob justice as the only way to reduce the security gap and relative deprivation of security (Adu-Gyamfi, 2014:87). In other instances, some people feel the strain because accused criminals

are being arrested today but are back on the streets the following day. Recent incidents of mob justice that occurred in Zandspruit near Honeydew, north of Johannesburg where four people were killed and five seriously injured are strong indicators of the incompetence of the police in combating criminal activities (SABC News, 2021).

According to Ikuomola (2011), police, in conducting their duties of combating criminal activities, need to be intellectual, courageous and diligent. Unfortunately, police are not provided with enough resources to conduct their daily tasks, and this has affected the police department negatively (ibid). It has also been revealed that lack of police professionalism and justice efficiency are factors that negatively impact human protection (SABC News, 2021). In an observational study, it was found that poor information-sharing and organizational culture affect police actions in security management (Ahmed, Muhammad, Mohammed & Idris, 2013). Ahmed et al (2013) add that police are not sufficiently equipped to perform their duty, and this leads to their ineffectiveness in conducting their job. They operate within very constrained resources, resulting in weak operational preparation and lack of equipment and logistical capacity (ibid). Faull (2007) argues that transitional nations, such as post-apartheid South Africa are difficult to police and present a series of obstacles to law enforcement agencies. On the other hand, lack of state control measures and subsequent increase in individual freedom give newly empowered societies more opportunities to participate in non-state activities, such as crime. Thus, in a newly minted democracy, violence associated with historically oppressive state police organizations is either inaccessible or heavily restricted. As a result, the convergence of these two patterns often results in increased crime at precisely the moment when law enforcement agencies are caught off guard and lacking a range of skills required to police a democratic society (Shaw, 2002b). In addition, police corruption is another stumbling block to efficient police work performance because it delays the extent to which the SAPS can perform their duty and build public trust and legitimacy (Faull, 2011).

Nonetheless, the most noticeable challenges that have been generated for policing include lack of occupational and operational autonomy for police, as well as an occupational culture that still maintains a colonial mindset, rather than adhering to obligations to duty, the rule of law, human rights enforcement and professional norms (Ashimala, 2014). Due to these factors, large numbers of victims of mob justice have been killed and severely injured. Statistics suggest that in South Africa, more than 800 individuals die in a year due to mob justice (Crime Stats SA, 2018). However, as evidenced by the proliferation of mob justice in contemporary South Africa, as long as communities feel vulnerable and there is an absence of a legitimate state police force that can effectively control crime, the disaffected public will certainly turn to other alternatives such as mob justice. Therefore, the rise in incidents of mob justice in Gqeberha, irrespective of the government appealing to the public to stop taking the law into their own hands, motivated the researcher to choose this research topic. The focus of this paper is, thus, on challenges that hinder effectiveness of police in combating mob justice, with the aim of suggesting measures to restore police integrity so that police administration can be efficient in eliminating the occurrence.

PROBLEM EXPOSITION

South African Police Service (SAPS) has a significant role to play in providing safety and security for all inhabitants of the Republic and upholding and enforcing the law. In Section 12 (1) (c) of

the Constitution of the Republic of South Africa, Act No. 108 of 1996, it is stated that every person has the right to freedom from all forms of violence from either public or private sources. Chapter 2 (Bill of Rights) of the Constitution (1996), Section 35 (3) (c) continues to highlight that every accused person has a right to a fair trial, which includes the right to a public trial before an ordinary court. The former prescriptions mean that everyone has the absolute right to safety, whether that person is accused of a crime or not and if accused of a crime, must be given an opportunity to prove his or her innocence in a court of law. Nevertheless, this is not the case, as occurrences of mob justice are reportedly on the increase in many townships in Gqeberha.

According to the survey conducted by the Department of Safety and Liaison (2016), there has been an increase in mob justice in the Eastern Cape since 2000. Crime Statistics demonstrate that between 1 April 2017 and 31 March 2018, 72 people were killed in the Eastern Cape in cases police classify as mob justice (Crime Stats SA, 2018). However, within the Eastern Cape, 47 cases were reported for the period 1 April 2018 to 31 March 2019 in the Motherwell Cluster in Gqeberha. Six (6) of these cases were reported in Ikamvelihle Police Station, fourteen (14) in Motherwell, three (3) in Swartkops, eight (8) in Kwadwesi, Kwazakhele and New Brighton Police Stations (Crime Stats SA, 2019). Given the difficulty of accessing reliable data and many incidents not resulting in death or not reported to the police, mob justice undoubtedly occurs with greater frequency than these statistically reflected. The statistics above attempt to provide an insight into how widespread such incidents are in the Eastern Cape despite the police effort. In addition, Crime Stats SA (2018) revealed that sixty-six percent (66%) of individuals mistrust police and that forty-six percent (46%) do not have confidence in the judicial process, so they take the law in their own hands.

Reports of such criminal acts against suspects have been increasing in media reports, and there is likelihood that this will be a growing trend if nothing is done to address police challenges (News24, 2018; Brodie, 2013: 1). Thus, this paper is attempted to address some of the challenges pertaining to the reduction of mob justice. Addressing police challenges in combating mob justice is of importance in contributing to the holistic understanding of bottlenecks that lead to an increase in mob justice. It is the observation of the researcher that in previous studies conducted on mob justice, the voice of SAPS members is absent. Therefore, the researcher argues that challenges faced by the police in curbing mob justice need to be taken into consideration to address the issue.

RESEARCH METHODOLOGY

This paper utilized a qualitative research approach. This approach, according to Babbie and Mouton (2004: 134), considers the narrative and descriptive essence of circumstances, relationships, or individuals, focusing on the interpretation of human values, behaviours, feelings, perceptions and emotions. In this study, such a qualitative approach was used to better understand participants' opinions, experiences and perceptions, with reference to challenges that hinder the effectiveness of police in combating mob justice in their policing areas. More so, qualitative research in this study was used to address questions about the phenomenon's dynamic existence and explain and interpret the phenomenon from the participants' perspective. A case study research design that is exploratory in nature was utilized in this study. A research design refers to a procedural plan, structure and strategy for a research project that the researcher uses to address the research questions (Kumar, 2011: 94). The use of a case study research design in this study enabled

the researcher to analyze and study the case of Gqeberha in greater detail with regards to exploring and gaining an understanding of participants concerning challenges confronted by police in combating mob justice. The target population of the study was drawn from four settings in Gqeberha, namely: Kwadwesi, Kwazakhele, Motherwell and New Brighton. A sample size of 48 respondents was utilized; it comprised sixteen (16) SAPS members selected based on their Public Order Policing status (POP). The sample further included eight (8) Community Police Forum (CPF) leaders who were chosen since they collaborate with SAPS members in building trust to fight crime at a local level. Pastors, Teachers, Civic and School Governing Bodies (SGBs) were among the twenty (20) community members selected for the study because of the important role they play in crime prevention. Lastly, the sample consisted of four (4) community leaders chosen because of their valuable responsibility in assisting to combat and solve crime and other social issues.

Table 1: The study sample

| SAPS Officials | CPF Leaders | Community Members | Community Leaders | Total |
|---|---|--|---|-------|
| Station Commanders; Vispol Commanders; Detectives; Sector Managers | Chairpersons; Secretaries | SGBs; Pastors; Civic | Councillors | |
| 4 (New Brighton) + 4 (Kwazakhele) + 4 (Kwadwesi Ext) + 4 (Motherwell) =16 | 2 (New Brighton) 2 (Kwazakhele) 2 (Kwadwesi Ext) 2 (Motherwell) = 8 | 5 (New Brighton) 5 (Kwazakhele) 5 (Kwadwesi Ext) 5 (Motherwell) = 20 | 1 (New Brighton) 1 (Kwazakhele) 1 (Kwadwesi Ext) 1 (Motherwell) = 4 | 48 |

Sampling procedures

This study's participants were chosen using purposive sampling, which is a non-probability sampling technique. Purposive sampling enabled the researcher to select a number of participants who could provide appropriate information on the subject. This sampling method was utilized to select respondents from SAPS, community members and CPF and community leaders, as they are well-informed about mob justice and challenges confronted by SAPS members in combating the occurrence since they are working together in preventing crime. Respondents were chosen purposefully for their experience in the phenomenon being studied.

Data collection techniques

Interviews were used as the research instrument in this study because they allowed respondents to freely express their insights and experiences without being constrained by predetermined questions. The aim was to acquire rich data that assisted to understand the participants' construction of knowledge and social reality. The advantage of using interviews is that they elucidate subjectively lived experiences and positions from the participants' perspective. The researcher had the opportunity to bring up observations and request interviewees to verify, refute, defend or expand on their input (Tracy, 2013: 132). The study utilized focus group interviews (FGIs) and semi-structured interview schedules to gather data. Semi-structured interview schedules were designed to gather data from key informants (KIs), which comprised SAPS members, CPF leaders and local community leaders. On the other hand, FGIs were established to acquire data from community members. The semi-structured interview schedules were in-depth and done on a one-on-one basis to develop detailed information about challenges confronted by

police in combating mob justice in each of the study areas. This allowed room for respondents to voice out their opinions; as such, more data was captured (Silverman, 2005: 155). Focus groups, on the other hand, assisted to gather in-depth qualitative data about community members' experiences and perceptions on mob justice as well as on challenges faced by the police in combating the occurrence.

Data analysis

The researcher analyzed data obtained for the study using the thematic method. Guest, MacQueen and Namey (2012) and Joffe (2011) define thematic analysis as a method of phenomenology that allows the researcher to identify, investigate, and record patterns in the data. Particularly, data was analyzed using Clarke and Braun's (2013: 120-123) six phases of thematic analysis. These phases included multiple levels of analysis, and it was critical for the researcher to follow all of them to properly analyze the data (Joffe, 2011). This method of analysis enabled the researcher to draw useful conclusions regarding the subject at hand.

ETHICAL CONSIDERATIONS

An ethical clearance certificate was received from the University of Fort Hare's Research Ethical Committee (REC) and the South African Police Ethics Committee before data was collected. Permission to conduct the study was also provided by the National Commissioner of Police, and participants who expressed an interest in taking part were given consent forms to sign before taking part in the interviews. Respondents were informed of the nature and the purpose of the study as well as their right to participate or withdraw. Furthermore, participants were also informed that their privacy would be protected and that their rights would be respected, that their identities would not be revealed and the information they provided would be kept private and used only for the purposes of the study.

RESULTS AND ANALYSIS

This section presents findings from data acquired through interviews (one-on-one interviews and FGIs carried out with the chosen participants from Gqeberha). The findings from in-depth interviews were analyzed thematically. Presented below is the analysis of the seven key themes that developed from the analysis. The themes include *verbatim* quotations (unedited raw data) from participants; italics are utilized for all *verbatim* quotes.

Theme 1: Challenges faced by police in combating mob justice

The findings from in-depth interviews revealed that challenges confronting the police in combating mob justice in Gqeberha are enormous. Primarily among these are the following: Reluctance of community members to provide information; overloaded police; underpaid police officers; lack of resources; attacks on police officers; hesitancy of community members to report mob justice cases; mob justice cases that occur out of sight; police corruption; an illiterate community and police officers who are not passionate about their jobs. In addition, some of these included the following: Ineffectiveness of the judicial system, lack of implementation, lack of cooperation, refusal of community members to be part of the CPF and community members who do not report crimes. All of these issues pose a significant challenge to efficient policing.

Sub-theme: The reluctance of community members to provide information

The participants highlighted that police have a challenge with communities and informers who are very skeptical about giving information to the police and who do not want to be witnesses, for fear of intimidation. They are afraid to be called ‘*impimpi*’ by their communities. To add, some participants mentioned that many people are reluctant to provide information to the police because they do not trust them as some are working with these criminals. Some of the comments were as follows:

"First of all, the community we are serving is very skeptical about even giving the information to the police because they are saying the police do not keep the information they give them. They go and tell these criminals that it is so and so who gave them the information. Secondly, I do not know which effective way can assist us to address this issue and build community trust between the police and the community because people do not trust the police and do not want to hear anything about them. The reason for this high crime rate is simply because people do not work together in fighting it. I do talk to them and they listen to me, but the minute I turn my back on them, they start to say he is wasting about our time, have you ever seen authentic police in this area?" (KI-B: 1).

"Police are always being called when the person is already dead or assaulted. Another thing is that they do not get witnesses who can stand in a court of law about what really happened. No one tells the police what really happened, and it is not like these people were not there. They witnessed everything, but it is always the case... I just arrived... I did not see anything or I was not there. You do not get to know what really happened because people are refusing to be witnesses of cases because once you are a witness, you become a target. Some families have lost their loved ones because of being witnesses. These criminals do get information... if how, I do not know. They give warnings to these people who are going to be witnesses to stop whatever they think of doing and if they refused, they kill them before they appear in court. As a result, in most mob cases, no one is arrested because no one wants to be a witness" (KI-C: 2).

Additionally, some participants emphasized that the main challenge the police are faced with is to have somebody who is in that group of people planning the occurrence of mob justice to inform them that this is what is going to take place so that before it happens, they are already there. According to a participant in an in-depth interview:

"As much as we do patrols in the areas, we are not always everywhere at the same time. So if people are deciding somewhere that we are going to this house at 00; 00 at night. We are going to get and burn this person, they have decided and have done their intelligence. Now when they execute, the challenge most of the time is having somebody in that group of people to inform us and say, this what is going to take place so that before even it happens, we are already there" (KI-D: 4).

Sub-theme: Overloaded police

On the issue of overloaded police, participants pointed out that due to shortage of resources, police are overloaded and incapable of investigating large numbers of cases/dockets. The responses below reveal more in this regard:

“As detective, we are overloaded. Let us say, for instance, here in this area, we had about 10 to 12 murders maybe a year. So if you allocate two detectives for the twelve. So suddenly with these three incidents of mob justice, we have now 15 murders. Therefore, the same two detectives must still do that and now they suddenly have two cases a month. So it is difficult for them to handle that and there is no new manpower coming in now to the detectives. So, to teach somebody to be a detective in investigative murders takes about 5 to 10 years. Only after 5 years can we start giving the new guy the investigation. Murder cases are done in high court, so is it very difficult. You must be well trained and well experienced. So, I can say there is workload with limited resources” (KI-C: 1).

“There is too much work for police as everything involves the police. Even though we blame them, but to be honest they have too much on their plate with limited resources and sometimes we do not report crime related issues to the police” (FGI-B: 5).

Sub-theme: Lack of resources

On the challenge of lack of resources, a number of participants mentioned shortage of vehicles and manpower. It emerged from the interviews that due to inadequate manpower, it becomes difficult sometimes for police to respond immediately to all crime scenes they are called to and in such cases, they have to prioritize. To add, if all vehicles are busy attending mob justice cases, they cannot respond to other crime scenes because they do not have standbys for mob justice cases. It also emerged that police have a challenge with the shortage of manpower in the detectives section, specifically trained manpower. However, new police recruits were reported as receiving very poor training, which leaves them largely unskilled and unable to perform some of their duties. Some of the comments on this issue were as follows:

“The members of the SAPS are responding but you will find that in a mob justice, one or two vans are responding, and then these vehicles are not enough to disperse those people. And then when these members of SAPS are there and then the numbers are not enough you have to mobilize in terms of getting POPs. In most cases, you find that the numbers of the police are not matching with the community we are policing. But sometimes the problem is not on the transport side but the repairs of vehicles - the garages. The problem particularly is the logistical problem with the police. The vehicles stay in the garage for a long time because of the difficulty of getting parts. As a result, you will find that we are struggling to get our working tools” (KI-C: 3).

“We have a challenge with the trained manpower. As detectives, we do not have enough manpower. So it is difficult for us to handle some of the cases in time. There is no new manpower coming in now to detectives. To teach somebody to be a detective in investigative murders takes about 5 to 10 years. Murder cases are done in high court so is it very difficult. You must be well trained and well experienced” (KI-C: 1).

“They do not have resources to do what is expected from them. I am talking about manpower and transport. Vehicles for example are not enough because the police do not only police mob justice but also other crimes. It is even difficult for them to visit their sectors, four people have to use one vehicle. They cannot be in two different sectors at the same time; instead, they must visit one and then another. As a result, other sectors are not being policed effectively” (KI-B: 2).

Furthermore, one participant said the following:

“Sometimes we do not have resources to maintain the situation and manage mob justice or the crowd where we use minimum force. We also face a challenge with investigation especially in our policing areas in Motherwell. Our policing areas have a lot of cameras, but the problem is that they are not recording. You can see what happened but it is not recorded. Not all places in PE have recording cameras. So, if we had that, we could be in a better position. They cannot put those recording cameras in certain areas because we do not know where crime is going to be committed. Sometimes it happens during the night and during the night, you cannot see anything” (KI-C: 1).

Sub-theme: Corrupt police officers

On this issue, some participants articulated that communities and other police have a challenge with some police officers who are working with criminals and who do not professionally conduct themselves. As a result, these practices, according to participants, have tarnished the image of the police and shattered their integrity. Some of the comments are as follows:

“There are also some police officers who are working with criminals and who do not have an approach. All these things cause the community members to distrust us” (KI-B: 4).

“These police officers are also criminals, and it is true they are criminals themselves and they protect each other. The management is aware of these allegations, but nothing is being done to arrest these police officers” (KI-B: 1).

“Some police officers do not professionally handle people's cases. Even if they know someone who committed a crime, they do not come forward and arrest the person. They just keep quiet as if they did not see anything. They are protecting these criminals. We are working with people who are not willing to work with us, and these people do not listen to our advice as people who are living in these areas” (FGI-D: 2).

Sub-theme: Ineffectiveness of judicial system

On this issue, it emerged that the police have a challenge with the Department of Justice that keeps releasing criminals on bail and probation etc. It was also highlighted that the bail itself is a challenge. Participants continued by expressing their confusion as to why persons who rape young girls and old women are granted bail. Some of the respondents had this to say:

“We have a challenge with the courts. Courts keep releasing the alleged criminals and this comes back to the police. The Department of Justice is failing the police and whatever the court does comes back to the police. When someone who has been arrested has been released, community members shout at the police and not the courts” (KI-C: 2).

“People are also complaining about criminals who get arrested today but are seen on the streets tomorrow. This also is a challenge to the police because they are fighting a losing battle. We report criminals today but tomorrow they are out committing other crimes. The government should stop this bail and sentence people to imprisonment or death penalty” (FGI-A: 2).

Sub-theme: Lack of leadership

On this matter, the participants stated that lack of leadership by station management poses a serious challenge in Motherwell Cluster police stations. The participants articulated that in meetings that they conduct with the management, promises are always made concerning the improvement of the station's performance, but there is nothing done to put those promises into practice. Some mentioned that even in those public meetings with community members, promises are made to support communities but when it comes to implementation, nothing is being done. As a result of this, many people do not attend police programs. As one community member in an interview said:

“Lack of leadership is another challenge the police are facing. There is no outcome in most of the meetings that we and the police hold with the management. They keep on having these meetings but there is no way forward. Management keeps telling people that they are going to do ABC, but when it comes to implementation, nothing is being done, and this also demotivates us from assisting them” (FGI-D: 3).

Theme 2: Impact of identified challenges on police work performance CPF Leaders

“Police performance is affected badly because in the event of mob justice, you have maybe two or three vehicles in the area. Those vehicles will be taken to hostage by that mob justice and police performance will be affected because police are not only policing mob justice. There are also other crimes happening there, and this one of mob justice becomes more serious and needs more police members. Because there is a life that is in danger, you cannot say you leave one vehicle with this mob because even the life of police officials will be in danger, so you keep as many vehicles or resources as you can. But in the meantime, complaints are outstanding in other areas, and service delivery is now poor there. There are crimes happening, there are murders that are happening, there are robberies that are happening other than mob justice and then the priority will be mob justice. Those people are also not happy with the police and will end up mobilizing themselves for mob justice because they are sick and tired of crime. Therefore, I would say due to insufficient resources, police are unable to render their services effectively e.g. be visible in all hot spot areas, respond to emergencies and arrest alleged criminals. All these things damage our image and cause communities to lose faith in us” (KI-C: 3).

“Unreported cases of mob justice by community members affect our performance because there is a crime committed and no arrest effected; we could not rescue the victims before getting injured/killed. So immediately a crime is committed, there must be an arrest. So, it is affecting our performance because no arrest is effected and if the victim injured stays five to six months in hospital, justice will not be served and that person with scars will seek revenge at the end of the day. So, it is a cycle of violence taking place” (KI-B: 2).

Theme 3: Measures undertaken to address identified challenges

When asked, how these challenges are addressed to improve police effectiveness, a significant number of participants asserted that the above-mentioned challenges are addressed by conducting awareness campaigns, *imbizos*, and public meetings in communities. It was also expressed that some of these challenges are addressed through meetings with station management and cluster offices, but nothing is being implemented; certain participants stressed that nothing is being done

to address the identified challenges because police are still overloaded and underpaid. On the other hand, some CPF members stated that they address these challenges with the Department of Safety and Liaison. The responses below tell more in this regard:

“To address these challenges we conduct public meetings, awareness campaigns and ‘imbizos’ because knowledge is the key. In these educational programs, we also invite this justice cluster, the Department of Justice and the Department of Correctional Services. But even in those ‘imbizos’, members of the community always point fingers at the Department of Justice. Because in ‘imbizos’ the police talk about their role and then the Department of Justice talk about their role with the department of Department of Correctional Services. Police will say, we arrest this one, taken to court and then the court is deciding on the release of this one. There are rights, they have the right to be bailed, they have the right to get free bail and there are also those minor sentences that they have to impose according to the constitution. The members of the community are not happy with that, they contest everything that is beyond our control. Because when you talk about the constitution and the rights, all those things are entailed in the constitution and police are not making the constitution; only politicians are making the constitution” (KI-C: 3).

“Councillors hold meetings with SAPS to find some strategies to address identified challenges, but the problem is that there is no implementation. They have been saying they are going to add more vehicles but up to now, there is nothing that has been done to fulfil their promises. The Minister only reacts after the incident, not before it occurs” (KI-B: 3).

Theme 4: Involvement of stakeholders in resolving mob justice

When asked about the stakeholders involved in resolving mob justice and their involvement, the majority of participants concurred that they have street committees and neighbourhood watch that assist by conducting patrols. On the other hand, other participants mentioned political organizations, correctional services, metro police, churches, social development and social justice that assist by organizing public meetings, *imbizos* and awareness campaigns with them. Some of the comments were as follows:

*“We have our structures called **sector forums, street committees and neighbourhood watch** that assist us in policing mob justice and other crimes. Even in our policing areas, these neighbourhoods watch help us by doing patrols and giving us information about people who are not happy with the way we do things. Then as the police, we go to the community the same day we hear the complaint and address that” (KI-B: 4).*

“The stakeholders involved in mob justice are departments that I am talking about ie the Correctional Services, Social Department and Department Of Justice. When we are having those ‘imbizos’ they come and talk to the community, and they are part of resolving mob justice. I am saying that we need the commitment from those influential members in the communities, those political leaders and those pastors, we need them to be involved” (KI-C: 3).

Theme 5: Description of police working conditions

When asked about the description of police working conditions, significant numbers of participants stressed that working conditions for police officers are strenuous and traumatic as a

result of long hours and excessive workloads. It was also expressed that police are in danger and exposed to traumatic events, which affects their well-being. However, only a minority of participants reported that their working conditions are tolerable. According to one of the key informants:

“It is very traumatic sometimes and dangerous because when you are the police, you are in a danger zone. Others are having psychological problems but fortunately, SAPS have an institution called employee health and wellness. Its programs are spiritual services, social work services, psychological services and work of life. But the problem is, even those people we are told to report our problems to, are having their stress. So, how is someone who is also stressed going to listen to me? As a result, due to these traumatic events, some police officers end up resigning” (KI-A: 1).

In the same vein, another key informant said:

“They are exhausting because we are working for long hours with too much work. You become stressed sometimes due things you are subjected to and unable to do anything when you get home. But as time goes by you, become used to the working environment. For example, for my stress, I must go to the gym and I must go to church” (KI-C: 4).

Another key informant corroborated when he said:

“As the police officer, you put your life on the line so that you can save lives. That is part of why everybody is here. Whenever it comes to protecting individuals or communities of South Africa, we have to come between the community and the perpetrators or criminals and find out if their property is safe. So, conditions are conducive and you will never know what to expect outside. There are channels whereby you can address those issues, for conditions to be tolerable” (KI-D: 4).

Sub-theme: Attacks on police officers

On the issue of attacks on police, participants stated that police officers are assaulted by community members when attempting to rescue victims of mob justice, which has made it impossible for them to rescue victims because the public wants to put the victims to death. According to a participant in an in-depth interview:

“It becomes difficult to control the crowd sometimes and in other cases, you community members do not want us to get in, they are hostile to us and even assault us because they want to finish that person. Maybe the reason the community is doing this, it does not have trust in the police or does not have trust in the justice system as a whole” (KI-A: 3).

Theme 6: Relationship between the police and the CPF/community leaders

When asked how they can describe the relationship between the police and CPF/Local councillors, all participants stated that even though there are certain challenges, police and CPF have an excellent relationship. On the contrary, some of the participants articulated that the police and councillors have a strained relationship. According to one of the key participants:

“We do work together with the police and we meet time and again. We engage each other in certain issues and assist each other whenever it is possible. Therefore, as the CPF, we

have that interrelationship with the police, but no relationship is free of problems” (KI-B: 1).

Similarly, another key informant added that:

“I can say it is not that bad; maybe they are just pretending as if they care. Because if you are an outspoken person like me, they put you under watch. So we are at risk because some of them are involved in these criminal activities or are close with people who are involved in these criminal activities and we cannot expose them to our station commander because we are going to be targeted” (KI-C: 2).

In a different perspective, another key informant said:

“There is no relationship between us and the police. We only meet when they have a problem that needs our attention. There are no weekly or monthly meetings that we conduct with them” (KI-A: 3).

Theme 7: Community-police relationship

When asked to describe a relationship between the police and the community they are serving, all the participants concurred that police-community relations are extremely bad in the Motherwell Cluster precinct. The responses below tell more in this regard:

“The relationship between the police and the community is not good as the community does not conduct any meetings and campaigns with them. When they call they do not arrive at times. The majority of the people also withdrawn as CPF representatives. The police forum also does not exist anymore. The communities want nothing to do with the police as they say they are useless, corrupt and do not fulfil their promises. Also, we used to invite the police to our meetings to express our concerns, but we were discouraged because they did nothing to address the issues we brought up. Hence, we consider embarking on strike” (FGI-C: 1).

“It is not good because there are still those who hate the police. Others hate the police because are disturbing them in their misdeeds. The majority of them also do not trust the police and do not report the crime to them. There is no cooperation between the police and the community” (KI-B: 3).

DISCUSSION OF FINDINGS

From the gathered qualitative data, it is clear that police officers are faced with numerous challenges in their attempt to combat mob justice in Motherwell Cluster precincts. It is said that in most instances, incidents of mob justice and other criminal activities are unreported, and communities hesitate to come forward for fear of being intimidated, thus posing a challenge to the police. These findings are similar to the findings of Buttle, Fowler and Williams (2010), who found that crimes such as those involving mob justice are not put on trial due to lack of credible evidence. This is mostly due to inadequate investigative methods, certain cases being unreported to police and communities reluctant to come forward to provide evidence. The participants also emphasized that the police challenge is to have somebody in that group of people planning mob justice to pre-warn them.

Furthermore, organization failures, especially inefficient management and ineffective justice department have been highlighted as one of the major factors affecting the police performance in combating mob justice. The station's management has been accused of not following through on its commitments whilst the Department of Justice has been reported to keep releasing criminals on bail and probation. Subsequently, literature such as that of Seekings (2007:189) has shown that bail is not seen as an approach of defending human rights or upholding the presumption of innocence unless proven guilty. Instead, it seems to be an obstruction to justice. Since it prevents punishment, public perception is that it provides space for more crime. On the other hand, Smith (2019) is of the view that the manner in which a democratic state is formulated gave rise to mob justice in South Africa. Smith believes that the mere reason the police are unable to combat mob justice is that the state provided strong procedural rights to accused criminals.

Another major impediment to police performance has been identified as corruption. On this issue, some police officers have been accused of working with criminals and acting in an unprofessional manner. These practices, as a result, have shattered police integrity. This is corroborated by Steinberg (2012), who stated that corruption jeopardizes public trust in SAPS and represent challenges of defining a new role and identity for a broad, highly structured policing organization operating in a troubled transitional environment. This finding is similar to findings by Faull (2011) who averred that corruption in the police department includes theft or extracting money from citizens and stealing or smuggling goods from alleged criminals, and this delays the extent to which SAPS can perform its duty and build public trust and legitimacy.

It has also been stated that underpayment is among one of the major challenges confronted by police. Police are reported to be working very hard and sometimes see themselves dealing with dangerous, life-threatening situations, but they are underpaid and this discourages them from doing their job effectively. This is in line with Westervelt (2012), which reveals that a better salary encourages people to do their job efficiently. Therefore, when they receive a small salary, they become reluctant to do their job. According to Westervelt, the salary of many police officers (excluding senior officials) is an insufficient source of income to provide for themselves and their families. As a result, the majority of them hardly resist bribes, which results in corruption within the police force.

Other challenges highlighted are lack of resources and overloaded police. The SAPS, like many other police forces across the world, is confronted with inadequate qualified personnel and resources. For instance, vehicle patrols in various police stations are restricted by lack of availability of vehicles and the minimum resources available are poorly serviced and scarcely fuelled due to lack of funds. Lack of reliable transport and poorly serviced vehicles mean that police will be slow to respond immediately to incidents of mob justice (Ashimala, 2014). This finding was also reinforced by Mlandu (2014), who argues that many police stations are deficient in resources and need manpower, which makes them overloaded and incompetent to perform important tasks effectively, such as patrolling crucial and distant neighbourhoods and responding quickly to emergencies.

The results also showed that illiterate communities pose another challenge in the effectiveness of the police in combating mob justice. The participants claimed that several community members do not comprehend the method in which the criminal justice system operates and are unaware of the dangers of mob justice. Yeboah-Assiamah and Kyeremeh (2014:9), writing in the Ghanaian

context, observed that the majority of citizens in developing African countries do not have a clear understanding of the legal system and how law enforcement agencies operate. They do not comprehend the value of giving alleged criminals a long time to prove their innocence in court. This may be attributed to the high rate of illiteracy and ineffectiveness of the National Commission for Civic Education (NNCE) to execute its statutory mandate of sensitization. This finding is also supported by Tankebe and Asif (2016) who articulated that people with limited educational backgrounds do not comprehend how the legal system works and have difficulty reading and interpreting the law, as well as knowing where to seek legal knowledge and acquire legal documents.

The findings also revealed that the police have a challenge with police officers who are not passionate about their job but joined the SAPS for the money. Omeje and Githigaro (2012:11) discovered in their research that certain police stations have officers who are less committed to policing duties. Some of these officers were recruited by senior officers or governing figures and perceive law enforcement to be their final career choice. Some of these officers are not genuine in their commitment to ethical work ethics, which is discouraging to officers who are passionate about their careers. Therefore, the police's ability to perform their duties is hampered, and the public suffers as a result of the police's failure to provide sufficient services. Participants also identified a lack of cooperation as a barrier to the police's effective operation. According to Schulhofer, Tyler and Huq (2011), effective policing necessitates cooperation and involvement of citizens; when the police are to combat disorder, they require the assistance of society. It is also said that for police to gain community trust and have a strong bond with the community, they must gain community interest and make contributions to the communities.

Other challenges that participants mentioned as hindering police ineffectiveness in preventing mob justice included the following: refusal of communities to join CPF, lack of implementation, attack on police officers, and mob justice cases which occur out of sight, under houses or in the bushes, places which are not easily accessible to drive. In addition, the findings demonstrated that the aforementioned challenges have a detrimental impact on police performance. According to the findings, police are unable to identify, apprehend and prosecute perpetrators of mob justice and alleged criminals due to poor police-community relations and the reluctance of community members and informants to provide information to the police. The findings also found that a lack of resources causes the police to be unable to provide effective service e.g. be visible in hot spot areas, respond to emergencies and arrest alleged criminals. This finding is similar to the findings of Martin (2012), Ashimala (2014), Omeje and Githigaro (2012:7) and Tankebe (2009a). These researchers all found that in South Africa, lack of resources is a challenge to surveillance, investigation and apprehension of wrongdoers. Particularly, lack of resources is seen in critical areas as a challenge to mob justice prevention. Similarly, Tengpongsthorn (2017) indicated that inadequate resources are not the only stumbling blocks to efficient police work performance, but they are also identified as an impediment to work performance efficacy in the inspection and enquiry divisions.

Furthermore, the majority of participants viewed that due to police work overload, the police are unable to conduct investigations thoroughly. As a result, many cases have been withdrawn due to a lack of evidence. Mlandu (2014) posits that many police stations are in shortage of manpower which makes them overloaded and incompetent to perform important tasks effectively such as

patrolling crucial and distant neighbourhoods and responding quickly to emergencies. Among other factors that have been reported to affect police investigation are un-recorded cameras, because without evidence, there is nothing the police can do to apprehend the suspects. Ashimala (2014) argues that police are not sufficiently equipped to perform their duty, and this leads to their ineffectiveness in conducting their jobs. They operate within very constrained resources, resulting in weak operational preparation and lack of equipment and logistical capacity. Inadequate equipment and work tools are not the only barriers to reducing efficacy of police work performance as they have also been identified as an obstacle to the effectiveness of work performance in the inspection and inquiry divisions.

The study also revealed that because of danger to which police officers are exposed, some officers do not want to work outside for fear of losing their lives, resulting in reduction in the number of officers needed to respond to mob cases. Ashimala (2014) identifies and explains poor working conditions as factors that have significantly tarnished the reputation and credibility of the South African police. As a result of unsafe working conditions, police officers are required to deal with risky, life-threatening circumstances without sufficient insurance to cover their families if something goes wrong. Hence, police become reluctant to respond to some of the violent crimes, thus undermining oversight and accountability. Other police officers, have been accused of failing to perform their duties effectively due to poor remuneration. Westervelt (2012) stressed that the salary of police officers (excluding the senior officials) is insufficient to provide for themselves and their families. As a result, the majority cannot resist bribes, which results in corruption within the police force. A better salary according to Westervelt, encourages people to do their jobs efficiently instead of collecting bribes. Additionally, the Department of Justice and Constitutional Development have been accused of tarnishing the police image by releasing wrongdoers on bail.

Consequently, with reference to the manner in which the identified challenges are addressed to improve police effectiveness, nearly all respondents articulated that the identified challenges are addressed through awareness campaigns, *imbizos* and public meetings with the station management, community members and other stakeholders. However, the only challenge they face is lack of implementation. Even SAPS members who articulated that they address some of these challenges through cluster-level meetings with station management acknowledge the issue of lack of implementation. Some claimed that nothing is being done to address the identified challenges because police officers are still overloaded and underpaid. In an attempt to address this occurrence, the study found that sector forums, street committees and neighbourhood watch are assisting the police in policing mob justice and other crimes. The following are some of the other stakeholders mentioned: political organizations, correctional services, metro police, churches, social development and social justice which assist by organizing public meetings, *imbizos* and awareness campaigns.

The study demonstrated that the police and the CPF in the Motherwell Cluster have good working relationships. Participants expressed their dissatisfaction with the relationship among the police, councillors and community members. Concerning the description of the police working conditions, the majority of participants stressed that working conditions for police are strenuous due to long working hours and the enormous amount of work. Further to the above, the participants highlighted that they are in danger and are subjected to traumatic events that have an impact on their well-being. Police across the world's living and working conditions are terrible. As a result,

they are forced to deal with vicious life-threatening circumstances without sufficient insurance coverage to offer their families in the event of death. As a result, police become reluctant to respond to some of violent crimes in many African countries, thus undermining oversight and accountability (Ojo, 2014:94; Greener, 2011).

CONCLUSION AND RECOMMENDATIONS

This study examined the perceptions and experiences of people on the challenges faced by police in combating mob justice in Gqeberha. The study established that the police officers in Gqeberha are confronted with enormous challenges in dealing with mob justice. Some of these challenges include communities and informants that are very skeptical about providing information to the police. Some police are described to be unproductive at work as a result of strenuous and traumatic working conditions. While some participants argued that these challenges cause police to be unable to conduct investigations thoroughly, the majority of participants stressed that these factors pose a significant challenge to efficient policing, resulting in proliferation in the number of mob justice cases. The study revealed that some attempts, such as awareness campaigns, *imbizos*, and public meetings, are made to address the highlighted challenges, but the problem is that the recommendations made from those gatherings are not being implemented. Consequently, it has been stated that the relationship between the police, the community and councillors is bad. Citizens are tired of current police officers and want police officers they can trust, as well as justice for those who break the law. Therefore, for citizens to get the type of police they desire intervention from the government, SAPS and the community is needed. The researcher is of the view that the integrity of the police can be re-established if challenges can be addressed. This paper has recommended that, firstly, South African Police Services officials from Public Order Policing indicated that, there is lack of resources. Based on this, the state government should supply the police with necessary resources to fulfil the necessities and demands of the communities. In addition, there should be at least two vehicles at each station reserved for emergencies. Police should also utilize motorcycles in places that are not easily accessible; these motorcycles will be helpful to reduce petty crimes and assist them to address community concerns timeously. It is very significant for SAPS to have transport at the police stations to combat mob justice rapidly and easily. Secondly, police officers' performance needs to be monitored weekly to ensure commitment and adherence to regulations when they are on duty. It was suggested that, the Department of Community Safety is suitable to monitor police agencies and assess their efficiency and effectiveness. The Department should ensure that they do follow-ups on meetings, campaigns and *imbizos*' resolutions or decisions. It is recommended that police officials receive necessary support in order to perform their duties with passion. Lastly, community members should also be inspired and motivated to join CPF, Street Committees, Community Patrollers or Neighbourhood Watch to establish an active relationship between the police and the community. By being part of these structures, community members could be informed of duties and tasks that they are expected to perform to combat mob justice as well as responsibilities of the CJS. More significantly, financial and material support to them may inspire and strengthen them to carry on their work in preventing mob justice and attract more people to join the above-mentioned structures and motivate existing CPF. In addition, CPF representatives, local churches, SGBs, councillors and local community leaders should motivate members of the community to be part of gatherings arranged to deal with crime issues in their communities. The above-mentioned stakeholders should

take a lead in campaigns against mob justice and encourage people to report incidences of mob justice.

THE EFFECTS OF COVID-19 ON THE MENTAL HEALTH OF STUDENTS IN THE FREE STATE PROVINCE, SOUTH AFRICA

T.D. Raphela

University of the Free State, Bloemfontein, South Africa

ABSTRACT

Studies around the world show that the COVID-19 pandemic has exacerbated mental health issues amongst individuals. However, the impact of COVID-19 on the mental health of university students in South Africa has not been reported. This study surveyed the mental health status of the University of The Free State students using two measures of mental health, i.e., anxiety and stress during the COVID-19 pandemic. An online survey was used to collect data from undergraduate and graduate students at the University. The survey was distributed via a bulk emailing system through the University gatekeepers. Student demographics and other variables related to mental health were analysed descriptively. Inferential statistics were used to analyse some of the most important variables linked to mental health. Mental health measurements (anxiety and stress) were used to realise the objective of the study. Three hundred and ninety-two (392) registered students at the UFS responded to the questionnaire. Most of the respondents $n=262$ were female, graduate students ($n=112$), between the age group 18-25 ($n=292$) studying on the Bloemfontein campus ($n=352$). The Generalised linear mixed model revealed that the interaction between gender and the students' faculty were significant predictors of students' anxiety and stress reports. Female students reported higher levels of anxiety and stress than male participants. The highest number of students from the Natural and Agricultural Sciences faculty reported anxiety, while the highest number of students from The Humanities faculty reported stress. Inadequate efforts to recognise and address mental health issues affecting university students in South Africa, especially during disasters or pandemics, can have long-term consequences on students' health and education, thereby affecting future generations. Many students need professional assistance to cope with psychosocial conflicts and mental disorders. Therefore, this study recommends that the University focus its mental health efforts more on the students from Natural and Agricultural Sciences and Humanities faculties to understand the reasons for the findings of this study and come up with effective intervention measures.

Keywords: COVID-19; anxiety, stress, mental health, students

INTRODUCTION

Since the World Health Organisation (WHO) declared COVID-19 on 11 March 2020 as a global pandemic (WHO, 2020), fear has gripped people and tested the ability of countries readiness to deal with the alarming levels of its spread and severity (Cvetković et al., 2020). World leaders realised that they were not at war with the Corona virus but with the human factor (Greg, 2020), the impact of COVID-19 on students, especially the mental health impacts have received little attention (Sundarassen et al., 2020). The impacts involve the study of how human beings behave physically and psychologically in response or relation to COVID-19 situations. Students' mental health has become a major national concern in developed countries like the United States of

America (Holm-Hadulla and Koutsoukou-Argyaki, 2015). Gallagher (2006) reported that staff members of university counselling services hold licenses to practice as psychologists, and anxiety and depression are experienced most by students. However, no one anticipated the far-reaching mental health issues to be exposed by COVID-19, especially in developing countries like South Africa. In South Africa, especially during disasters, there are more pressing issues such as people's livelihoods being affected; therefore, mental health issues are often ignored. Therefore, this study seeks to gauge how COVID-19 has affected the University of the Free State (UFS) students, focusing on two main measures of mental health, anxiety and stress (Keckojevic et al., 2020). In addition, the study also focused on knowledge of COVID-19 mode of transmission, reports on the perceived level of risks, and fear of contracting COVID-19. The literature scan did not show any study that has documented findings on mental health issues among University students in South Africa. More studies focused on the mental health of health care professionals (Naidu, 2020; Kim et al., 2020), leaving out other vulnerable groups, i.e. students. This study tries to fill this gap, drawing insights from the literature to conceptualise the problem, focusing solely on anxiety and stress reports from the UFS students.

LITERATURE REVIEW

Mental health issues are among the most critical health problems experienced by humans, particularly students in Higher Education Institutions (HEI) (Quinn et al., 2009; Levecque et al., 2017). However, the extent of the problem has not been established in developing countries (Baloran, 2020). Therefore, case-specific studies are needed from HEI in these countries, with different socio-economic issues, to enable a global understanding of mental health issues across developing countries, particularly in HEI. In most developing countries, most mental health problems are reported to occur within the health sector (Lai et al., 2019). Little attention is paid to university students' mental health, especially during disasters, even though the Royal College of Psychiatrists (2003) reported an increasing number of students in higher education experiencing mental health problems. For example, in French Universities, Wathelet et al. (2020) students demonstrated anxiety, traumatic stress disorder, depression, and suicidal thinking in 28%, 22%, 16%, and 11% of students, respectively. Furthermore, Holm-Hadulla and Koutsoukou-Argyaki (2015) demonstrated that student mental health and specialized services helping students to come to terms with psychological problems are an important professional issue worldwide. Moreover, students' flexibility has been reported to be increasing worldwide, which will eventually exacerbate physiological problems and mental disorders (Pakenham et al., 2020). Detailed reports of psychological problems besetting university students are found in letters, autobiographies and notes of politicians Holm-Hadulla et al., 2010). For example, Prince (2015) reported increasing mental health issues among students in the United State of America (USA). Increased anxiety, depression, traumatic stress, and even suicidal thinking associated with COVID-19 quarantine has been amply documented in various countries and populations, but such studies are lacking in Africa.

Mental health and COVID-19

Many studies have linked fear and knowledge to mental health issues (Mertens et al., 2020; Salisbury, 2020; Thombs and Tao, 2020). Mertens et al. (2020) reported increased fear to be related to perceived risk and health anxiety in a social media survey of 439 participants. Several studies

reported individuals who are vulnerable to COVID-19 to experience high levels of fear, which could lead to acute and ongoing anxiety (Salisbury, 2020; Thombs and Tao, 2020; Ahorsu et al., 2020; Brooks et al., 2020). In the face of the COVID-19 pandemic it is important to identify factors that make people particularly vulnerable to developing mental-health issues and to gauge these issues case by case (Millroth and Frey, 2021). In this study UFS students' responses to anxiety and stress were measured.

Mental health measures and COVID-19

Females are regarded as the most vulnerable group in line with the sphere project standards. In addition, Eaton-Stull (2021) reported gender as a precipitator of Post-Traumatic Stress Disorder, with females as the most vulnerable gender compared to their male counterparts. In a meta-analysis study, the prevalence of anxiety in 17 studies with a sample size of 63,439 was found to be 31.9% in a systematic review (Salari et al., 2020). Women were also found to be more anxious 62% and more likely to adopt precautionary behaviour, such as avoiding going to the hospital as observed in a study done in Pakistan (Rabbani et al., 2022). In Iraq, females were found to be a significant independent factor for higher anxiety and stress levels (Kamal and Othman, 2020). In the USA an online study also reported that women had more negative emotional experiences during the pandemic to a point where they became more anxious (Alsharawy et al., 2021). The female gender was a significant predictor of health anxiety in a study done in Saudi Arabia (Al-Rahimi et al., 2021). A correlation has been reported between the level of vulnerability and anxiety during the COVID-19 pandemic (Al-Rahimi et al., 2021).

METHODOLOGY

Research design

The research design is a systematic plan and procedure to be followed in integrating the different components of the study coherently and logically to effectively address the research problem and answer the research questions (Leedy & Ormrod, 2015). This study adopted a mixed method research design to obtain qualitative and quantitative data. The quantitative component of the study was used to collect numeric data and the qualitative component was used to collect text data (Dubois, 2018). A mixed methods study, therefore, allows for a more holistic approach to research (Leedy & Ormrod, 2015).

Sampling method

This study conducted an anonymous Google form survey, distributed online using the UFS, bulk email system, with the assistance of the gatekeeper between December 2020 and January 2021. The survey was distributed with a consent form, ethical clearance obtained from the UFS and a gatekeeper permit.

The survey targeted all the undergraduate and graduate students at the UFS. The sample size included all the students who had been registered for the 2020 and 2021 academic year to gather maximum possible data to enhance generalizability. The Google form survey setting was adjusted to allow a participant to fill the form once, after submission of the form, the participant could not take the survey again. However, if the respondents wanted to make amendments on their responses, an option was given where they could anonymously contact the principal researcher.

This study used the Cronbach Alpha to test the reliability of the questions (Inal et al., 2017). The questionnaire was piloted with 10 students before administration to check for validity and reliability. For the pilot study, a preliminary analysis of the collected data was carried out to check the reliability and validity of the questionnaire. The questionnaire used for this study was developed by the researchers and was ethically approved by the University of the Free State Human ethics committee (ETHICS NUMBER). Data was retrieved from the online survey, entered into Microsoft Excel and then imported into R Statistical Software (version 4.0.4; 2021-02-15) for statistical analysis while text analysis was done for the qualitative part of the study to derive themes that were surfacing from the gathered data.

Research instrument

A semi-structured questionnaire survey was used to collect data for this study. Questions that were not answered in the survey were considered non-responses and were excluded from the analysis.

Quantitative data was captured in Microsoft Excel and analysed using Microsoft excel and R statistical Programme, while text analysis was used for the qualitative data of the study to derive themes that surfaced from the data gathered. Most questions allowed for dichotomous answers, coded as yes and no. Few trichotomous questions required yes, no, no response/not sure and/or do not know from the questionnaire.

Data collection

To address mental health issues amongst students, students' opinions and perceptions were prioritized. The study then collected data using a semi-structured questionnaire online survey, distributed electronically amongst the UFS students. The questionnaire was chosen to gather in-depth information on the students' perspective regarding their mental health issues since the start of COVID-19. To address mental health issues the researchers worked in collaboration with the GUniversity gatekeepers to develop a secure anonymous space accessible only to participating students and the lead researcher. Mental health issues are very sensitive, and a secure space was needed for this study. Students were invited to participate in the study through an initial email sent to the UFS gatekeepers describing the study's aim and inviting them to participate.

Students were invited to contact the main researcher if they felt uncomfortable completing the questionnaire. Interest in the study from students was much greater than anticipated with more than 300 students responding to the study amidst reports of people being COVID-19 fatigued. The study considered of ethical considerations, and the University of the Free State Human ethics committee gave ethical approval to the research. The participants were treated as confidential as possible, and the anonymity of the participants was preserved. Finally, information collected through the questionnaire was analysed using R statistical software program (See data analysis below).

Data analysis

Descriptive summaries concerning demographic information of the students and some level of knowledge about COVID-19 were used together with inferential statistics to:

- a) Assess the relationship between university majors of the students (grouped into the seven academic faculties of the UFS as the dependent variable) and students' reports of three independent variables:
- level of personal risk of acquiring COVID-19.
 - fear of contracting COVID-19; and
 - knowledge of the time it takes for COVID-19 to show symptoms after infection.

These issues were considered separately during the survey, a multinomial logistic regression analysis fitted from the *nnet* package in R (version 4.1.10 (2021-05-18)) with a multinomial function was applied to assess the relationship between the variables mentioned above. This statistical test was performed to understand the COVID-19 risk knowledge, and perception amongst the UFS students based on their faculty.

- b) To investigate the mental health of students during the COVID-19 pandemic, mental health measures (anxiety and stress) were used (Kecojevic et al., 2020) and gender as the most important demographic when it comes to mental health (Eaton-Stull, 2021; Wathélet et al., 2020; Browning et al., 2020). Two separate GLMMs fitted via maximum likelihood in R (version 4.1.0; 2020-05-18) with a *glmer* function and a poisson distribution (*lme4* package, Bates et al., 2015) were applied to assess the student's mental health status during the COVID-19 pandemic. The mental health measures were analysed separately as response variables. Gender and the interactions between gender and the students' faculty were set as predictor variables. For all models, student numbers were used as a random factor (intercepts only). The mental health measures could be influenced by the number of student reports per faculty since most students were from the NAS faculty (See results below). The model was checked to see if it was appropriate for the variables described above, and a suitable model was used, based on the plot of the residuals against the fitted values from each model. P values were generated using likelihood ratio tests. For all models, significance was determined using Wald (χ^2) statistics. All graphs were produced using a *GGplot2* package from the R software and tables were produced using Microsoft Excel 2010.

RESULTS

Demographic characteristics

The study participants were predominantly female, 66.8% between the 18-25 age group, 73.7% doing their post-graduate studies, 28.6% in the Bloemfontein campus, with no Biological and Health science university exposure. Most of the students, 70.2% of the respondents did not have either Biological or Health sciences exposure before they enrolled at the UFS. Furthermore, 79.1% of the respondents did not take any Biological or Health sciences majors at UFS (Table 1).

The issue of Biological and Health Science exposure in terms of COVID-19 is a very critical one, since exposure before or in a tertiary institution might assist in predicting the mental health based on respondents' basic knowledge of viruses even though COVID-19 is new. However, since most of the respondents did not have exposure to Biological and Health Sciences and not majoring in either led this study to investigate gender as the most critical demographic variable regarding mental health issues (Eaton-Stull, 2021). Eaton-Stull (2021) reports gender as one of the precipitators of post-traumatic stress disorder (PTSD).

Table 1. Demographic characteristics of the University of the Free State students in Bloemfontein, South Africa.

| Variables | Categories | Responses (N, %) |
|---|-------------------|------------------|
| Age groups | 18-25 | 289 (73.7) |
| | 26-35 | 70 (18) |
| | 36-45 | 18(5) |
| | 46-55 | 10(3) |
| | 56-65 | 2(0.5) |
| | NA | 3(0.8) |
| Gender | Male | 121 (30.9) |
| | Female | 262(66.8) |
| | Other | 4(1.02) |
| | Prefer not to say | 5(1.3) |
| Biological and Health Science University exposure | Yes | 111(28.3) |
| | No | 275(70.2) |
| | NA | 6(1.53) |
| Level of study | 1st year | 11(2.8) |
| | 2nd year | 111(28.1) |
| | 3rd year | 78(19.9) |
| | 4th year | 80(20.4) |
| | Post-graduate | 112(28.6) |
| Biological and Health Science as a University major | Yes | 78(19.9) |
| | No | 310(79.1) |
| | NA | 4(1.0) |
| Campus | Bloemfontein | 352(89.8) |
| | South campus | 7(1.8) |
| | QwaQwa | 33(8.4) |

Knowledge about COVID-19

The ('yes', 'no', maybe/not sure/no responses) of students to two questions from the survey were analysed to measure students' knowledge on COVID-19, as detailed below:

Students were asked whether COVID-19 can be transmitted by direct contact with an infected person; respiratory droplets and contact with contaminated surfaces as reported by the World Health Organization (WHO, 2021). Most students (n=372) reported maybe when asked if they knew how COVID-19 is transmitted, followed by (n=13) students who reported that they knew how COVID-19 is transmitted. A negligible number of students (n=7) did not know how COVID-19 is transmitted, as reported by WHO (2021). Furthermore, most students, (n=211) reported that were at risk of contracting COVID-19; followed by (n=103) who reported maybe and (n=78) who reported not being at risk of contracting COVID-19 (Figure 1).

Figure 1: The number of reports on knowledge of the mode of COVID-19 transmission (top) and risk of acquiring or contracting COVID-19 (bottom) of the University of the Free State students in South Africa.

Level of risk, fear and knowledge of COVID-19

The multinomial analysis revealed student responses on the level of risk of acquiring COVID-19 (Wald $\chi^2_{56} = 59.88$, $P=0.336$), fear of contracting COVID-19 (Wald $\chi^2_{56} = 75.33$, $P=0.310$ and knowledge of the time it takes for COVID-19 to show symptoms after infection (Wald $\chi^2_{56} = 45.215$, $P = 0.848$) were not influenced by students' university majors based on their faculties. However, most of the students reported that the risk of contracting COVID-19 is medium, with most of the students reporting this medium risk coming from the NAS faculty (Figure 2). Furthermore, some students reported to be a little bit afraid of contracting COVID-19, but most of the students from the NAS faculty reported to be very afraid of contracting COVID-19. The majority of the respondents reported that COVID-19 takes up to 14 days to show symptoms, with most of the students coming from the NAS Faculty (Figure 2).

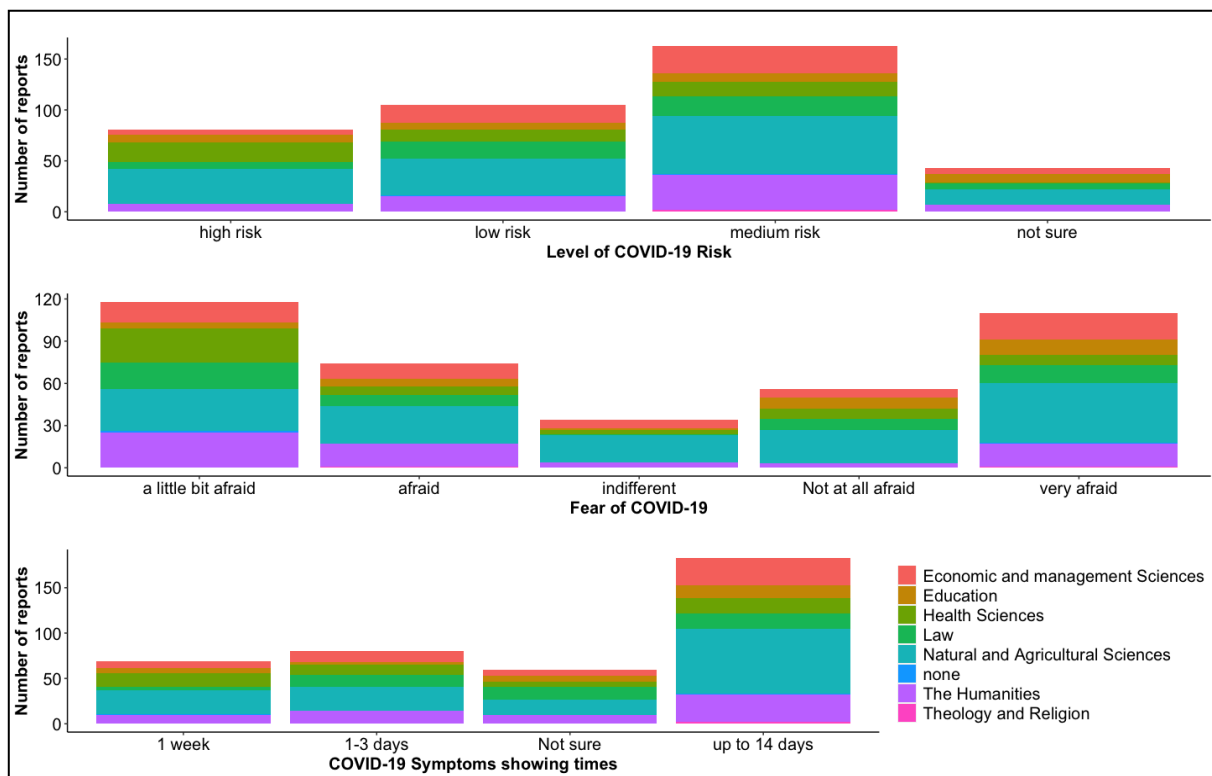

Figure 2: The number of reports per faculty on the level of personal risk of acquiring COVID-19 (top), fear of contracting COVID-19 (middle) and the time it takes COVID-19 to show symptoms (bottom) of the University of the Free State students in South Africa.

Variation in students’ responses for anxiety

Gender (Wald $\chi^2_3 = 63.8, P < 0.001$), faculty (Wald $\chi^2_7 = 145.6, P < 0.001$) and the interaction between gender and faculty (Wald $\chi^2_{11} = 23.5, P = 0.014$) were significant predictors of students’ anxiety. Significant higher reports of anxiety were from females, followed by males, students who chose other as their gender and those who chose not to reveal their gender. Furthermore, the highest number of students from the NAS faculty reported feeling anxious during the COVID-19 pandemic, followed by students from EMS, Law and Health Sciences with equal reports and Edu. A very negligible number of students did not report their faculty and were the same number of students as the ones from TAR with regard to reporting whether they felt anxious during the COVID-19 pandemic (Figure 3). Moreover, the highest number of anxiety reports was from females as compared to males across all faculties, with the highest number of reports coming from females in the NAS faculty (Figure 3). The number of students who responded to the survey per faculty did not influence the anxiety reports (Wald $\chi^2_1 = 0.7, P = 0.392$).

(Abbreviations for Figures 3 and 4: PNTS=Prefer Not To Say; All faculties of the University are abbreviated on the figure as follows; Edu=Education; EMS=Emergency Management Sciences, HS=Health Sciences, NAS=Natural and Agricultural Sciences, NF=No Faculty reported, TAR=Theology and Religion, TH=The Humanities)

Figure 3: Anxiety reports during COVID-19 by gender (top left), faculty (top right) and the interaction between gender and faculty (bottom) by the students of the University of the Free State, South Africa. Boxes show medians (solid black line across the box) and 1st (top box) and 3rd (bottom box) quartiles. Whiskers show total range and dots outside of boxes indicate outliers.

Variation in students' responses for stress

Gender (Wald $\chi^2_3 = 50.7$, $P < 0.001$), faculty (Wald $\chi^2_7 = 150.6$, $P < 0.001$) and the interaction between gender and faculty (Wald $\chi^2_{10} = 23.4$, $P = 0.09$) were significant predictors of students reports on stress. As with anxiety, significantly higher stress reports were from females, followed by males, students who chose other as their gender and those who chose not to reveal their gender (Figure 4). Interestingly, the highest number of students from the TH faculty reported that they felt stressed during the COVID-19 pandemic, followed by students from NAS, Law, EMS, HS, Edu faculties. A very negligible number of students did not report their faculty and they were the same number of students as the ones from TAR regarding reporting whether they experienced stress at some point during the COVID-19 pandemic (Figure 4). Furthermore, the interaction graph shows more reports of stress were from females from the NAS faculty followed by males (Figure 4). The number of students who responded to the survey per faculty significantly influenced the stress reports given by students (Wald $\chi^2_1 = 1$, $P = 0.015$).

Figure 4: Stress reports during COVID-19 by gender (top left), faculty (top right) and the interaction between gender and faculty (bottom) by the students of the University of the Free State, South Africa.

DISCUSSION

A negligible number of students of the UFS (n=13 out of 392 responses) reported that they knew how COVID-19 is transmitted is worrisome, especially with most of the respondents (n=121) reporting that they are at risk of contracting COVID-19. Knowing the mode of transmission of a virus can to some extent reduce the risk of any individual. In addition, the response is surprising because of the availability of information regarding COVID-19 from reputable websites like WHO where students can get information. In contrast to the study findings, a study in the United States of America (USA) revealed that college students in New Jersey had a fundamental knowledge of COVID-19 transmission and tended to use and trust the official sources and changed their behaviour by following public health recommendations (Keckojevic et al., 2020). Nevertheless, the contradictory reports from students in America and South Africa cannot be reduced to tertiary affiliation only, other socio-demographic factors come into play, especially in South Africa as a developing country. For example, the USA, compared to South Africa, has free fiber for students and everyone to access news at any time they want. Even though not investigated by this study, internet access and load shedding could be some of the main reasons most of the students did not bother to visit the WHO website or any other reputable site to look for information.

Level of risk, fear and knowledge of COVID-19

The faculty that students are enrolled at did not determine the students' responses when they were asked on their level of risk of acquiring COVID-19. Their fear of contracting COVID-19; knowledge of the times it takes for COVID-19 to show symptoms after infection indicate and remove the bias associated with the highest number of respondents coming from the NAS faculty. However, most of the students from the NAS faculty reported medium risk of contracting COVID-19, this was surprising, as this faculty has students majoring in hard sciences, in particular biological sciences, where there is more awareness of viruses as compared to other academic faculties of the UFS. Furthermore, most students reported to be a little bit afraid of contracting

COVID-19, but most of the students from the NAS faculty reported to be very afraid of contracting COVID-19. This could be justified by the fact that most courses in the NAS faculties required students to be in the laboratories for experiments; fear of the unknown amidst the COVID-19 pandemic could have exacerbated the highest reports of contracting COVID-19 in this faculty as compared to other faculties. This finding could be attributed to the fact that some of the majors in this faculty include laboratory work, whereby social distancing could sometimes not be avoided due to common use of other materials and apparatus and the time it takes for experiments to run.

The majority of Health Science students reported being slightly afraid of COVID-19 after the NAS respondents. Lessons can be learnt from the Health Science students as some of these students were and are still working in hospitals for their practical modules. However, this finding could be attributed to the Personal Protective Clothing the Government provides the Health Sciences students with during their practical's, therefore reducing their risk level. Most of the respondents reporting that COVID-19 takes up to 14 days to show symptoms, could emanate from the fact that since the start of COVID-19 people who were in closed contact with a COVID-19 infected person were encouraged to isolated for 14 days. Students could not fail to be aware of this information on the mode of COVID-19 infection as this was practiced in most of their homes as the COVID-19 variants were emerging.

Variation in students' responses for mental health measures

Gender, faculty and the interaction between gender and faculty were significant predictors of students' reports on stress and anxiety during the COVID-19 pandemic. It was not surprising that female respondents reported significantly higher anxiety and stress reports. Studies reported females as the most vulnerable to anxiety as compared to their male counterparts (Browning et al., 2021; Al-Rahimi et al., 2021; Wathélet et al., 2020). A study in French universities reported females being more anxious during the COVID-19 pandemic (Wathélet et al., 2020). Furthermore, the highest number of students from the NAS faculty reported that they felt anxious at some point during the COVID-19 pandemic. Even though in the GLMM model NAS students' reports had the highest number, this finding was not surprising. The NAS students due to the nature of most of the courses in their faculty might have perceived themselves as vulnerable to COVID-19 as compared to students from other academic faculties. The finding of the highest number of students from The Humanities faculty reporting stress, was surprising and could not be explained by the study data. This study chose not to explore the majors in The Humanities faculties to further gauge student perceptions from this faculty, but rather to recommend for further studies.

CONCLUSION

In conclusion, compared to their male counterparts, women were reported to experience a disproportionate burden of the psychological impact of the COVID-19 pandemic (Rabbani et al., 2022). Also, in Asia, a study showed female students experienced a higher level of psychological impact (Browning et al., 2021). Therefore, mental health communication by the UFS and relevant stakeholders in healthcare targeting women should be considered a mental health risk reduction measure during disasters.

Based on the problematic knowledge of the respondents on the mode of COVID-19 transmission by a negligible number of the respondents, this study concludes that several modes of knowledge

and information dissemination should be considered in disaster situations. For example, theatrical knowledge dissemination could be very appealing to students. Even though the UFS was and still is consistent in sharing COVID-19 news on their official platforms, most students ignore the news. Indeed, a lot of literature reported students to be COVID-19 fatigued because of higher levels of anxiety (Browning et al., 2021; Labrague and Ballad, 2020; Wathelet et al., 2020). This could be one of the reasons the students' knowledge of COVID-19 about the mode of transmission was negligible in this study.

Although it is recognised that each institution of higher learning is different, the study captures an issue that might be similar in most institutions of higher learning in South Africa. Even though the findings of this study are not generalisable across South Africa or Africa as a continent, they offer an understanding of the anxiety and stress level by gender and faculties within the UFS which may need to be investigated in other institutions in South Africa. Given that the project was self-funded, other organizations for Mental Health and Well-Being in South Africa could use this finding to create a framework to take actions on addressing student mental health across the country. The study acknowledges that the UFS has done much work to address mental health issues amongst its community during the COVID-19 pandemic. However, it appears from the students' perspective in this study that there are still issues that still need to be addressed, such as gender if the UFS is going to effectively meet the needs of students with mental health problems.

RECOMMENDATIONS

Even though COVID-19 is new, this study recommends that role players and stakeholders in Disaster Management should in future come up with several alternative measures to disseminate disaster information, especially in a disaster where lockdown and isolation measures are keeping people, especially students glued to their screen. This study recommends further studies to investigate the report from The Humanities students about high stress levels.

THE CHANGES IN EVENING SCREEN EXPOSURE AND SLEEP DISTURBANCES DURING THE COVID-19 PANDEMIC

T.D. Raphela

University of the Free State, Bloemfontein, South Africa

M.K. Maisiri

ABSTRACT

University students are within the group of vulnerable populations that experience great challenges. Social developmental transition and excessive use of smart devices coupled with the COVID-19 pandemic seem to have exacerbated their vulnerability. This study aimed to explore how individuals' sleep quality and sleep duration can be affected in disaster situations. Most importantly, this study assessed whether screen exposure before bedtime would affect the sleeping times of the University of the Free State (UFS) students amidst the COVID-19 pandemic while also determining whether electronic device usage would affect the sleep quality of the students. This study reports the results of an online -based-survey distributed among UFS students regarding evening screen exposure and sleep disturbances during the COVID-19 pandemic. The researcher used the UFS gatekeeper process to submit electronic questionnaires to students' email addresses. The descriptive summaries of the demographic characteristics of the students were represented by frequencies. The Generalised Linear Models (GLZs) were used to assess variations in students' responses by 1) electronic device usage and 2) sleep quality during the COVID-19 pandemic. In addition, the Generalised Linear Mixed Model (GLMM) was used to assess whether students' screen exposure before bedtime affected their sleep patterns during the pandemic. The R Statistical software was used to analyse all statistical data. Descriptive statistics showed that 256 students responded to this study, whereas inferential statistics revealed an effect of screen exposure, electronic device use, and sleep quality of the students and student responses separately. In line with studies around the world, this study revealed that most of the students reported reduced sleep quality together with reduced sleep duration since the beginning of the COVID-19 pandemic. In addition, most students reported that their screen exposure had increased since the beginning of the COVID-19 pandemic. Furthermore, many of the students reported that their screen exposure had affected their sleep time during the pandemic. Students who reported increased electronic device usage also reported decreased sleep quality. This paper showed a sleep-screen exposure link exacerbated by the COVID-19 pandemic among UFS students. While the government of South Africa is in the process of drafting policies to allocate free 10 gigabytes of data for its citizens, the new policies can take into consideration the findings from this study.

Keywords: Screen time, screen-based devices, sleep implications, students, COVID-19, Public Sector and HR: Education Culture and society

INTRODUCTION

South Africa went into lockdown on the 26th of March 2020, to combat the spread of COVID-19 infections and to reduce pressure on healthcare systems (Egbe & Ngobese, 2020). Hence, people were confined to their homes with limited access to many services, thus resulting in huge

complications. Lockdown measures, i.e., home confinement as a measure to mitigate the spread of the coronavirus, implemented in South Africa was a great strategy, but studies reported that it affected the physical and mental well-being of individuals (Erren et al., 2020; Wang et al., 2020; Zhao et al., 2020). Social isolation as a measure to reduce infection curtails access to family, friends, and other social systems that can cause loneliness, anxiety, and depression (Zhao et al., 2020). This motivates the greater use of digital devices that may alter and compromise sleep patterns (Majumdar, Biswas & Sahu, 2020).

The use of social media and digital devices provides a platform to ameliorate social isolation, but when used close to bedtime can negatively affect sleep among young adults (Orzech et al., 2016). Extensive use of social media by young adults between 18 and 35 years of age is linked with an elevated tendency to develop sleep problems and disruption of daily activities (Sivertsen et al., 2019). Additionally, excessive screen time is associated with problematic behaviors attributed to sleep disturbances and inattentiveness (Demirci et al., 2015; Parent et al., 2016; Tamana et al., 2019).

Worldwide, the COVID-19 pandemic has been reported to exacerbate community sleeping disorders (Altena et al., 2020; Majumdar et al., 2020; Salfi et al., 2021). However, an area that has received little attention in the COVID-19 literature is screen exposure among university students, especially in South Africa. Few studies have investigated the effects of COVID-19 on sleep but mostly focused on the medical staff or those who have been exposed to or suffered from COVID-19 and not students in institutions of higher learning (Brooks et al., 2020).

This study assessed the effects of electronic device usage before bedtime on the sleep quality of UFS students during the COVID-19 pandemic. This study wanted to demonstrate that in any disaster situation, individuals' sleep quality and sleep duration can be affected differently. Most importantly, the study assessed whether screen exposure affected the sleep times of the UFS students during the COVID-19 pandemic while also gauging if electronic device usage affected the students' sleep quality.

LITERATURE REVIEW

Many factors can affect sleeping patterns (Feng et al., 2014), but the role of mobile use in causing sleep problems has gained attention in the past few years (Akçay & Akçay, 2018). The current meta-analysis by Carter et al. (2016) showed that bedtime use of electronic devices was positively associated with poor sleep quality and excessive daytime sleepiness. Various mechanisms of mobile use at bedtime can cause poor sleep quality (Mireku, 2019). The blue light emitted by the screens of mobile phones contributes to poor sleep quality (Shechter, 2018). Moreover, mobile phones receive and transmit signals through radiofrequency electromagnetic fields (Patel, 2018), which can pass through the skull and reach the brain (Tattersall et al., 2001). Therefore, this technology may pose dangers to human health; of particular interest are its effects on sleep parameters and sleep electroencephalogram (Loughran et al., 2005).

College students are vulnerable populations that endure many challenges, risks, and social developmental transition (Feng, Du, Ye & He, 2014). The excessive use of smart devices (Feng, Du, Ye & He, 2014) coupled with the COVID-19 pandemic seems to exacerbate these challenges. Among a sample of 200 Stanford university students, 10% and 34% in the US acknowledged full addiction and almost addiction to iPhones, respectively (Kandell, 1998). Likewise, 11.2% of 276

African American college students showed a high level of Smartphone addiction (Lee, 2015). Whereas in Africa, a study in Nigeria found that university students in Southeast Nigeria spend a lot of time on screen-based devices (Adum, 2016).

Increased communication is associated with the use of screen and internet-based technology by college students (Clark et al., 2004). In addition, students use new media and screen devices for academic purposes (Adum, 2016). Aside from the many benefits of ubiquitous screen-based devices and technologies, the problem of overuse, compulsive use, pathological use, over-exposure, abuse, or addiction to them is becoming increasingly apparent (Davis, 1999). Students represent a particularly vulnerable group to problems associated with new media use (Adum, 2016). This is because students at least have a mobile phone. In contrast, others who do not have personal computers access them in their hostels, libraries, and computer labs or patronise cybercafes (Kandel, 1998).

Studies reveal that some kinds of effects could exist, based on the usage pattern for these technologies (Gustafsson, 2009; Linn, Almon & Wolfsheimer, 2012). Studies in the United States indicated low student awareness of the negative impact of too much screen time, and these studies did not focus specifically on health impacts (Anderson, 2001; Scherer, 1997). There is a need to ascertain students' awareness of the impact of exposure to screen-based devices, especially before bedtime. Huijberts et al. (2022) reported that the influence of pre-bedtime light-emitting screen use on sleep duration might partly attribute to differences in screen activities. However, Staple et al. (2021) reported that evening and bedtime screen use was related to more parent-reported sleep problems.

METHODOLOGY

Research design

In this study, a mixed-method research approach was adopted. The mixed method approach is embedded in the pragmatist research paradigm. It employed a qualitative approach to identify the thoughts and responses of students from the UFS to understand how their electronic devices use during the COVID-19 pandemic affected their sleep. To observe South Africa's lockdown regulations, such as social distancing, data for this study was collected using an online survey. The survey was made available online for a month after the study was approved. The sample included graduate and undergraduate students registered for the 2021 academic year at all UFS campuses.

The quantitative data from the completed survey was collected in Microsoft Excel version 16.39 and analysed using R Statistical programming language. The study calculated frequencies by using descriptive statistics to analyse the demographics of students and applied inferential statistics to analyse information sought questions.

Sampling method

The survey targeted UFS students across all campuses. The survey was sent to all UFS students registered for 2021 through the UFS gatekeeper's process to adhere to the POPIA Act. To avoid Pseudo replication of the results, participants could only submit one questionnaire. An option to make amendments was made available through the principal investigator should the participant want to make changes in their responses. Cronbach Alpha was used to test the questions (Inal et

al., 2017). The questionnaire for this study was also ethically approved by the University of the Free State Human ethics committee. Data were retrieved from Google forms as CSV files and analysed using R Statistical software (version 4.0.4; 2021-02-15).

Ethical consideration

This study received ethical approval from the UFS Human ethics committee (UFS-HSD2020/2149/21). In addition, the participants confirmed that they understood that their participation in the study was voluntary and was free to withdraw at any time without giving a reason and without any negative consequences. They were also free to not answer any particular question or questions. They were free to decline or withdraw by contacting the principal investigator at any time using the details provided on the survey. Furthermore, the participants confirmed that they understood that their responses and personal data would be kept confidential and gave permission for the principal investigator to have access to the data; most importantly, all participants agreed to take part in the study. To further ensure validity and reliability, the Google form responses of the 256 students were automatically time and date-stamped.

Research instrument and data collection

An online semi-structured e-questionnaire survey developed using Google forms by the principal investigator was used to collect data for this study. Questions that were not answered in the survey were considered non-responses and were excluded from the analysis. Data from the Google form was downloaded in CSV format and uploaded to R Statistical Software Programme. Only three questions across the study allowed for dichotomous answers, coded as yes and no; the rest were information-seeking questions related to the study objectives. There were no trichotomous questions that required yes, no, no response/not sure, and/or do not know from the questionnaire as the study wanted to get honest opinions of the student's on-screen use. Surprisingly, the interest in the study was much greater than anticipated, with more than 200 students responding to the questionnaire amidst informal reports that students are fatigued with COVID-19 studies.

Data analysis

Frequencies were used to report descriptive summaries of the demographic characteristics of the students. Data were mostly categorical and did not meet the assumptions of normality (Shapiro-Wilk test). Accordingly, nonparametric analyses were used. The Generalised Linear Models (GLZs) were applied first to assess variations in students' responses by 1) electronic device usage and 2) sleep quality of the UFS students during the COVID-19 pandemic.

The numerical frequencies of students' reports were analysed separately with the GLZs, with a *glm* function and Poisson distribution. Electronic device usage and sleep quality were reported separately as independent variables, with the number of student responses as the outcome variable for the two models. Data for this study is presented as bar plots. Secondly, the Generalised Linear Mixed Model (GLMM) fitted via maximum likelihood with a *glmer* function and a Poisson distribution (lme4 package, Bates *et al.* 2015) was applied to assess whether students' screen exposure before bedtime affected their sleep patterns during the COVID-19 pandemic.

The number of student responses was set as the outcome variable whereas screen exposure, sleep times, and the interactions between screen exposure and sleep time were set as predictor variables. The number of students was included as a random factor (intercepts only) because the student

responses could be influenced by the number of student reports for each predictor variable. The model fit for the variables described above was checked and used based on the plot of the residuals against the fitted values from each model. The P values were generated using likelihood ratio tests. For all models, significance was determined using Wald (χ^2) statistics, and the probability level was set at $P \leq 0.05$. All statistical tests and graphs were produced using a GGplot2 package from the R Statistical software (version 4.1.0; 2020-05-18).

RESULTS AND DISCUSSION

A total of 256 students responded to the survey and all confirmed that they read and understood the information sheet explaining the study. As expected, most of the respondents were female (n=181) followed by males (n=73) and two respondents preferred not to reveal their gender.

Interestingly, a significant number of respondents preferred not to divulge their age (n=27). This could be because of the stigma attached to the overuse of cell phones among students (Gajecki et al., 2014). It can only be assumed that older students are the ones who did not reveal their age since most of the younger students (n=190) reported their age followed by the students who still fall under the youth category 26-35 (n=36). It is reported across the world, that university students, particularly the youth, are glued to their small screens for a greater part of the day (Demirci et al., 2015; Parent et al., 2016; Tamana et al., 2019), now with the COVID-19 and online learning, these reports hold more truth. The survey was designed to make all questions compulsory not allowing the participants to see the next question before they answer the current one. Therefore, the researcher can only assume that the study title was a giveaway for some participants not to divulge their age or rather it was just the participants not willing to give their age group.

As expected, a very negligible number (n=8) of 1st-year students responded to the survey. However, most of the participants (n=85) were post-graduate students of the UFS, followed by the 2nd (n=62), 4th (n=52), and 3rd (n=49) year students respectively. Furthermore, most participants (n=227) were students at the Bloemfontein campus (n=233). In contrast, a negligible number (n=29) of the participants were both staff and students of the UFS from QwaQwa (n=22), and the South campus had only one respondent. All 256 participants reported that they have electronic devices and the majority reported delayed bedtime during the COVID-19 pandemic (Figure 1).

Figure 1: Responses of bedtimes amongst the University of the Free State students in Bloemfontein, South Africa, during the COVID-19 pandemic.

Variation by electronic device use and sleep quality

The electronic device use (Wald $\chi^2_3 = 2124.4$; $P < 0.001$) and sleep quality of the students (Wald $\chi^2_3 = 1799$; $P < 0.001$) were significant predictors of the number of student responses with the highest number of students reporting increased electronic device use followed by those students who reported their electronic use behavior to have not changed during the COVID-19 pandemic. As expected, a negligible number of students reported that their electronic usage had reduced during the COVID-19 pandemic (Figure 2). Furthermore, the majority of the students reported their sleep quality to have decreased during the COVID-19 pandemic, students also reported increased sleep quality and insomnia during the pandemic (Figure 2).

Figure 2: Frequency of the responses by electronic device use (A), Sleep Quality (B) amongst the University of the Free State students in Bloemfontein, South Africa, during the COVID-19 pandemic.

Variation in screen exposure and sleep time

Students were asked about their screen exposure before their usual bedtime, and most of the students reported that their screen exposure had increased since the start of COVID-19 (Figure 3). As a follow-up question, students were asked if they thought their screen exposure was affecting their sleep time during this COVID-19 pandemic, and most students reported yes (Figure 3).

Furthermore, screen exposure (Wald $\chi^2= 10.286$, $P=0.005$) significantly predicted the students' responses, but sleep time (Wald $\chi^2_1= 0.942$, $P=0.331$) and the interaction between sleep exposure and sleep time (Wald $\chi^2_2= 0.9,67$ $P = 0.616$) were not significant predictors of students' responses. There were significantly higher student reports of increased screen exposure before bedtime during the COVID-19 pandemic (Figure 3).

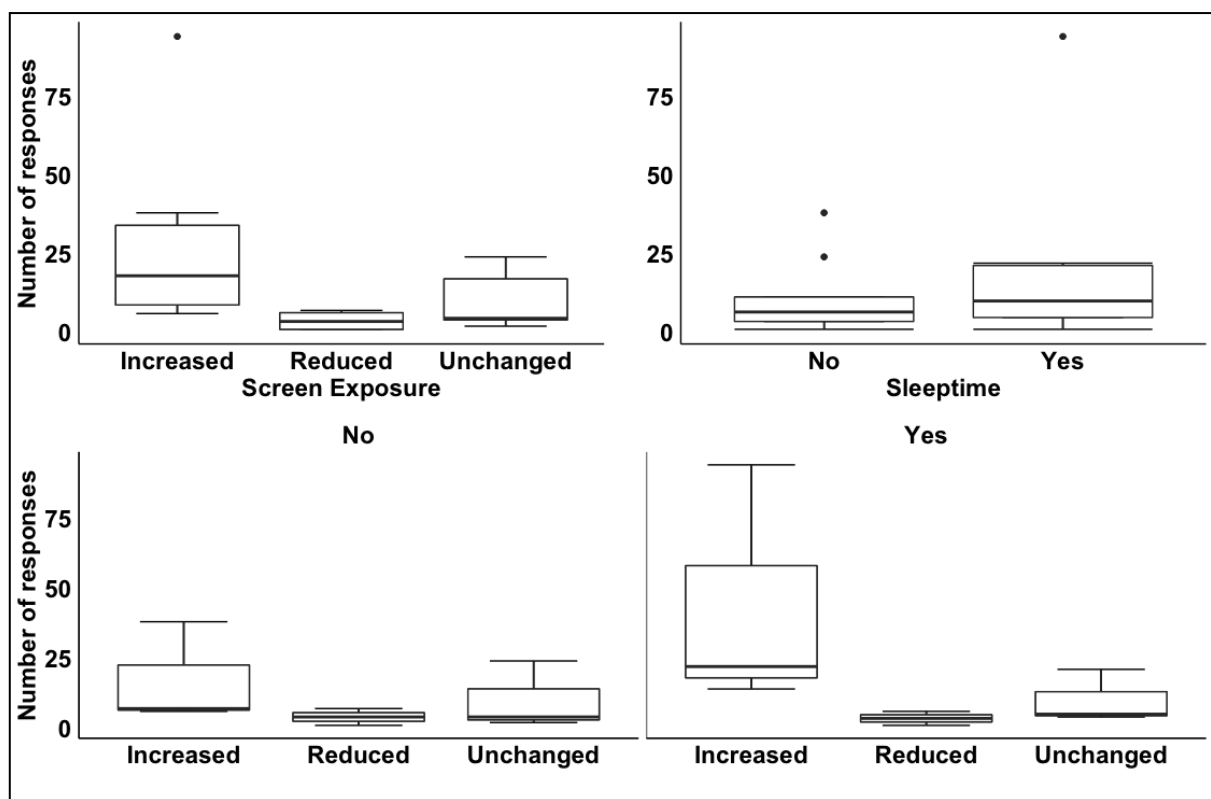

Figure 3: Students' reports by screen exposure (top left), sleep time (top right), and the interaction between sleep exposure and screen time (bottom) by the students at the University of the Free State, South Africa.

Boxes show medians (solid black line across the box) and 1st (top box) and 3rd (bottom box) quartiles. Whiskers show the entire range, and dots outside of boxes indicate outliers. Dots outside boxes indicate outliers.

A significant difference was recorded for reduced screen exposure and no significant differences were recorded for all the other variables and the interaction thereof (Table 1).

Table 1: The output of the GLMM model about age comparisons of the students for reports of screen exposure and sleep time. Significant predictors are shown in bold.

| Variables | Estimate | Std error | Z value | P value |
|---|---------------|--------------|---------------|---------------------|
| Screen Exposure: Reduced | -1.359 | 0.868 | -1.566 | P < 0.001 |
| Screen Exposure: Unchanged | -0.620 | 0.734 | -0.845 | P = 0.398 |
| Sleep time: Yes | 0.951 | 0.700 | 1.359 | P = 0.174 |
| Screen Exposure: Reduced* Sleep time: Yes | -1.063 | 1.225 | -0.868 | P = 0.386 |
| Screen Exposure: Unchanged* Sleep time: Yes | -0.782 | 1.021 | -0.766 | P = 0.444 |

DISCUSSION AND CONCLUSION

Consistent with studies around the world, this study revealed that most students reported reduced sleep quality since the beginning of COVID-19, followed by those with reduced sleep duration (Scherer, 1997; Linn, Almon & Wolfsheimer, 2012; Anderson, 2001; Gustafsson, 2009). In addition, most students reported increased screen exposure, which has affected their sleep time since the start of COVID-19. Furthermore, students who reported increased electronic device usage reported decreased sleep quality.

Variations in electronic device use and sleep quality

The results showed that the sampled students in this study who reported increased screen exposure also reported decreased sleep quality was not surprising since studies reported an increase in electronic devices usage during the COVID-19 pandemic (Bruni et al., 2021; Kennedy & Grandner, 2021; Salfi et al., 2021). Salfi et al. (2021) reported decreased sleep quality among 2 123 Italians with increased electronic device usage in 2021. In addition, a meta-analysis by Carter et al. (2016) showed that bedtime use of electronic devices was positively associated with poor sleep quality and excessive daytime sleepiness. The relationship between electronic device usage and sleep quality existed for University students as they had to attend online classes during the COVID-19 pandemic while in lockdown. Furthermore, Shechter (2018) reported that a major contributing factor to poor sleep quality is the blue light emitted by the screens of mobile phones. Some studies have found that exposure to blue light increases brain alertness (Lockley & Gooley, 2006) and can stimulate cognitive functions, leading to poor sleep quality (Daneault et al., 2014). The highest number of UFS students that reported increasing their screen usage before bedtime is worrisome not only for poor sleep quality but also for the student's health. Demirci, Akgönül & Akpınar (2015) found that in Turkey, depression, anxiety, and sleep quality among students were associated with Smartphone overuse.

Another study in Serbia reported a statistically significant and strong positive correlation between medical students' sleep quality and the use of mobile phones (Randjelović, 2019). Poor sleep quality has emerged as a relevant public health problem in technologically advanced societies (Cheung & Wong, 2011). Participants in this study who reported increased screen exposure also reported decreased sleep quality. The issue of electronic device use is very sensitive and cannot be tackled at an institutional level, especially in South Africa as a developing country. This study recommends policy interventions on these issues even though they will be difficult and controversial to handle even in developed countries.

Delayed bedtime during COVID-19

Most of the students reported delayed bedtime, followed by those who reported reduced sleep duration during the COVID-19 pandemic. Sleep problems during confinement may be an important issue for everyone, but some individuals are at a higher risk of developing sleep problems than others (Altena et al., 2020). Walker & Van Der Helm (2009) reported sleep as an important factor in regulating behavior and emotions. The novel coronavirus pandemic and its uncertainties coupled with periods of isolation were too challenging for university students, as shown by the research findings in terms of sleep.

Variation in screen exposure and sleep time

Students were asked about their screen exposure before their usual bedtime, and most reported that their screen exposure has increased since the start of COVID-19. Consistent with studies around the world, this finding was not surprising (Altena et al., 2020; Killgore et al., 2020; Kocevskaja et al., 2020; Majumdar et al., 2020). For example, a study in India reported excessive screen exposure by office workers and students (Majumdar et al., 2020) during the COVID-19 pandemic. Altena et al. (2020) **reported** that screen exposure might affect sleep quality when used close to bedtime.

These unprecedented changes occurred quickly because of the COVID-19 pandemic and lockdowns coupled with restrictions. The University of the Free State students is not an exception. Moreover, the stay-at-home regulation coupled with social distancing to curb the spread of the pandemic came with many challenges for students. These are the most socially vulnerable groups in communities as most students are still in their teenage years and very hormonal. Social contact is very vital to them. Therefore, most students reporting increased screen exposure during the pandemic could have been compensation for limited social life.

As a follow-up question, students were asked if they thought their screen exposure is affecting their sleep time amidst the COVID-19 pandemic and most students reported yes. Sleep times play an important part in humans because of the fundamental role sleep plays in emotion regulation. Therefore, sleep disturbance can directly affect the next day's emotional functioning (Pinto et al., 2020). The COVID-19 situation was likely to affect many factors that influence sleep quality (Kocevskaja et al., 2020).

RECOMMENDATIONS

This paper showed a sleep-screen exposure link exacerbated by the COVID-19 pandemic among UFS students. Although this is a very controversial issue that needs to be handled by institutions worldwide, unstructured mitigation from the Government of South Africa through policies can try to reduce the impact of this link among students in South Africa. For example, the Government of South Africa is in the process of drafting policies to allocate free ten gigabytes of data for its citizens, and the new policy can make use of the findings of this study.

THE ASSOCIATION BETWEEN GENERATION Y STUDENTS' GLOBAL CONSUMER ACCULTURATION AND MATERIALISTIC INCLINATIONS IN SOUTH AFRICA

A.L. Bevan-Dye

North-West University, Vanderbijlpark, South Africa

ABSTRACT

Materialism tendencies, generally perceived as being a negative trait, are often attributed to Western mass-media, global marketing activities and other global consumer acculturation forces. However, empirical evidence supporting these allegations is limited, begging the question of whether such allegations are real or mere conjecture. Indeed, the findings from a recent study encompassing USA and Japanese Millennial consumers indicate that only openness to the global consumer culture contributes significantly to materialism tendencies, and only so in the individualistic and ethnically diverse context of the USA sample. In line with these findings, this study sought to investigate the association between South African Generation Y students' global consumer acculturation and materialistic inclinations. Data were gathered from a sample of 564 university students from three South African public universities. The questionnaire included four global acculturation dimensions and one materialism dimension. Data analysis included principle component analysis, descriptive statistics, a one sample t-test, confirmatory factor analysis, path analysis and an independent samples t-test. The findings indicate that South African Generation Y students exhibit materialistic tendencies and are cosmopolitan, open to the global culture and are exposed to both Western mass-media and global brand advertising. Path analysis results indicate that only openness to the global consumer culture is a statistically significant predictor of their materialistic tendencies and that while exposure to Western mass-media contributes to those tendencies, it does not do so in a significant manner. Furthermore, cosmopolitanism and exposure to global brand advertising had a negative, although insignificant, influence on materialism. In terms of gender differences, female respondents were significantly more open to the global consumer culture than the male respondents and indicated a significantly greater exposure to both Western mass-media and global brand advertising. The study's findings suggest that allegations that global consumer acculturation forces contribute significantly to Generation Y consumers' materialistic inclinations are more speculation than truth.

Keywords: Materialism values; global consumer acculturation; Generation Y, South Africa

1. INTRODUCTION

The concept of an increasingly homogeneous global consumer culture emerged against the backdrop of McLuhan's (1962:31) foretelling that the evolution of technology and electronic media would reduce the world into a metaphorical "global village" and Levitt's (1983) assertion that modernity, driven by technological advancements in communications, transport and travel, would cause national and regional differences to give way to a global communality in markets. Based on Robertson's observations of the "crystallization of the world as a single place" (1987a: 38) and "the emergence of the global human condition" (1987b: 23), Featherstone (1990) indicates

that the world's progressive interdependence and interconnectedness leads to global ecumenism and to the production of a global culture. In terms of consumption-related behaviour, Alden *et al.* (1999) explain that globalisation gives rise to a global consumer culture, with globally-shared consumption symbols and aspirations. Typically, this acculturation into the global consumer culture is taken to mean acculturation into Western-style consumption patterns (Czarnecka *et al.*, 2020; Sobol *et al.*, 2018; Robertson, 1987a.). The implication here being that globalisation and the forces of global consumer acculturation, particularly global brand advertising and exposure to Western media have a more insidious side, namely the global spread of consumerism, and conspicuous, compulsive and impulsive consumption; that is, the spread of materialistic values (Cleveland *et al.*, 2021; Czarnecka *et al.*, 2020; Cleveland & Bartsch, 2019; Sobol *et al.*, 2018; Strizhakova & Coulter, 2013; Paek & Pan, 2004). While theories of this effect abound (Paek & Pan, 2004), empirical evidence of it are contradictory. Cleveland *et al.* (2021) found that at the aggregate eight country sample level, with the exception of cosmopolitanism, there was a strong positive relationship between global acculturation forces and materialistic values, but that the predictive nature of those forces on materialistic values decreased substantially on the individual country level. Lysonski and Durvasula (2013) found only some of the global acculturation forces to have an influence on materialistic values in their Nigerian youth study, and report that this influence was moderate at best. In another study, Gonzalez-Fuentes (2019) found that openness to the global consumer culture was the only positive and only statistically significant predictor of materialistic values in his USA consumer sample and the only positive but non-significant predictor of those values in his Japanese consumer sample.

Against the background of these contradictory findings, this study set out to investigate the link between materialistic values and global acculturation forces in the context of South Africa, as an emerging economy. The target population selected for the study was Generation Y university students. Several studies (Sobol *et al.*, 2018; Carpenter *et al.*, 2013; Cleveland *et al.*, 2009) indicate that younger, more educated individuals exhibit a greater degree of global consumer acculturation than older, less educated individuals. As such, Generation Y university students were viewed as an ideal target population for testing the influence of global consumer acculturation forces on materialistic values in the South African context. Specifically, the study aimed at determining the extent to which Generation Y students exhibit materialistic values and identify with the global consumer culture, and whether the global acculturation forces of openness to the global culture, cosmopolitanism, and exposure to Western mass-media and global brand advertising influence their materialistic values. In addition, the study sought to determine whether Generation Y males and females differed significantly in terms of their level of materialistic tendencies and the extent to which they identify with the global consumer culture.

2. LITERATURE REVIEW

Culture plays a salient role in consumption-related behaviour (McCracken, 1986), and the progressive interdependence and interconnectedness between world cultures has fostered the emergence of the global consumer culture (Featherstone, 1990), characterised by globally-shared consumption symbols and aspirations (Alden *et al.*, 1999). Acculturation into this global consumer culture refers to the process by which individuals acquire the knowledge, skills and behaviours synonymous with this transnational, non-regional global consumer culture, with the purported drivers of this acculturation process being openness to the global consumer culture,

cosmopolitanism, self-identification with the global consumer culture, English language use, traveling experiences and attitudes, exposure to global mass media and exposure to global multi-national marketing activities (Cleveland & Laroche, 2007). One of the criticisms levelled against this acculturation into the global consumer culture is the theory that the process kindles and/or exasperates materialism, with predominantly Western consumer ideologies spreading from advanced Western economies to emerging and developing economies (Cleveland *et al.*, 2021; Czarnecka *et al.*, 2020; Cleveland & Bartsch, 2019; Sobol *et al.*, 2018; Strizhakova & Coulter, 2013; Paek & Pan, 2004).

Materialism refers to a devotion to worldly possessions and the avid desire to consume for non-utilitarian reasons such as status and novelty (Richins & Dawson, 1992). Generally, materialism has a negative connotation and is associated with envy, possessiveness, covetousness and avariciousness (Belk, 1985). Materialistic tendencies are linked to status consumption, conspicuous consumption, compulsive consumption and impulsive consumption (Czarnecka *et al.*, 2020; Podoshen & Andrzejewski, 2012). Richins and Dawson (1992) conceptualise materialism as a personal value and indicate that individuals with a high level of materialistic values view the acquisition of possessions as central to their lives and as essential to their happiness, and tend to assess their own and others' success in terms of the number and quality of possessions accumulated. Global brand marketing efforts and Western media promoting a hedonistic lifestyle and conspicuous consumption in particular are thought to trigger consumerism desires and encourage consumers in emerging economies to emulate their counterparts in the consumer societies of advanced Western economies (Cleveland *et al.*, 2021). Nevertheless, empirical evidence supporting the allegation that global consumer acculturation forces create and/or intensify materialistic tendencies across the globe are limited and contradictory, begging the question of whether such allegations are real or mere conjecture.

In their study of consumers in China, Fastoso and González-Jiménez (2020) indicate a statistically significant association between the latent factors of cosmopolitanism and materialism. This relationship is in contrast to the findings reported by Cleveland *et al.* (2009), who indicate a negative relationship between cosmopolitanism and materialism in seven of the eight countries that they sampled. However, they did find a strong positive relationship between these two factors in their South Korean consumer sample. In their study of Nigerian youths, Lysonski and Durvasula (2013) report that openness to the global consumer culture and exposure to Western media had a small but statistically significant positive influence on materialism, while cosmopolitanism and exposure to global brand advertising had a non-significant positive influence on those values. In their eight country study, Cleveland *et al.* (2021) report that openness to the global culture had a statistically significant positive influence on materialism in Mexico and India, a non-significant positive influence in Greece, Sweden and South Korea, and a non-significant negative influence in Canada, Chile and Hungary. Cosmopolitanism had a non-significant positive influence on materialism in Mexico, Hungary and South Korea, a non-significant negative influence in Canada, Chile, Greece and India, and a significant negative influence on materialism in Sweden. Exposure to Western media had a significant positive influence on materialism in Canada, Mexico, Chile, Greece, Hungary, Sweden and South Korea, but a non-significant negative influence on those values in India. Exposure to global brand advertising had a statistically significant positive influence on materialism in Greece and India, a non-significant positive influence in Canada, Mexico, Chile and Sweden, and a non-significant negative influence in Hungary and South Korea.

In his two country study, Gonzalez-Fuentes (2019) reports that openness to the global consumer culture had a statistically significant positive influence on materialism in the USA and a non-significant positive influence in Japan. He reports that cosmopolitanism, exposure to Western media and exposure to global brand advertising all had a negative, though non-significant influence on materialism in both the USA and Japan.

Against the backdrop of these findings, this study tested the most relevant global consumer acculturation forces as drivers of materialistic values, namely openness to the global culture, cosmopolitanism, exposure to Western media and exposure to global brand advertising.

3. RESEARCH METHODOLOGY

This study was guided by a descriptive research design and utilised a single cross-sectional sample design.

3.1 Sampling and data collection

In line with the objective of testing the influence of global acculturation forces on materialistic values, the target population for this study was Generation Y university students. The assumption here being that younger and better educated individuals have a stronger affinity with the global consumer culture. Specifically, the target population was defined as male and female 18 to 24 year-old students registered at South African public universities. Taking into account cost constraints, the sampling frame was constrained to university campuses situated in the Gauteng province, which is the most populace province in the country (Statistics South Africa, 2020). Thereafter, judgment sampling was used to select three campuses in the province, with the criteria being to ensure that students from each of South Africa's three main types of public universities, namely universities of technology, comprehensive universities and traditional universities, were represented in the sample. Applying a mall-intercept style approach, fieldworkers administered the survey questionnaire to a non-probability convenience sample of 600 students at the three selected universities' campuses (200 per campus).

3.2 Research instrument

A self-reporting survey questionnaire was used to record the required data. The questionnaire included a section designed to capture demographic information as well as a section designed to measure relevant global consumer acculturation forces and materialism values that included scales from published studies. Materialistic values were measured using the three-item scale developed by Richins (2004) that included the items of "I like a lot of luxury in my life", "I admire people who own expensive homes, cars and clothes" and "I'd be happier if I could afford more things". The global acculturation forces deemed relevant to this study included openness to the global culture, cosmopolitanism, exposure to Western media and exposure to global brand advertising. The five-item scale used to measure openness to the global consumer culture was an extended version of the Cleveland and Laroche (2007), the added items based on the idea that the youth generally share similar leisure interests, concerns, hopes and ambitions across the globe (Frank & Watchravesringkan, 2016; Wee, 1999). These five items included University students like me generally "enjoy the same leisure activities across the globe", "have the same hopes and ambitions across the globe", "listen to the same type of music across the globe", "watch the same type of films/TV programmes across the globe" and "experience similar concerns and worries across the

globe”. Cosmopolitanism and exposure to Western media were measured using the scales from the Cleveland *et al.* (2013) study. Cosmopolitanism included the four items of “I enjoy being with people from other countries to learn about their views and approaches to life”, “I like to observe people of other cultures to see what I can learn from them”, “I enjoy exchanging ideas with people from other cultures or countries” and “I am interested in learning more about people who live in other countries”, while exposure to Western media included the three items of “I enjoy watching Hollywood films”, “I often watch Hollywood TV programmes” and “Some of my favourite actors/actresses are from Hollywood”. Exposure to global brand advertising was measured using Durvasula and Lysonski’s (2016) abridged version of Cleveland and Laroche’s (2007) scale, which was adapted to include exposure to global brands on television, social media sites and in print media. The three items included in this scale were “When I am watching TV, I often see advertisements for global brands”, “When I am on social media sites, I often see advertisements for global brands” and “When I read newspapers/magazines, I often see advertisements for global brands”. Responses to these 18 scaled-response items were recorded on a six-point Likert-style scale.

3.3 Data analysis

The captured data were analysed using IBM’s Statistical Package for Social Sciences (SPSS) and Analysis of Moment Structures (AMOS), Versions 27. Data analysis included frequencies and percentages, principal component analysis using varimax rotation, descriptive statistics, a one sample t-test, an independent samples t-test, confirmatory factor analysis and path analysis using the maximum likelihood approach, and measures of reliability and construct validity.

4. RESULTS

Field work resulted in 564 completed questionnaires being collected from the 600 distributed. Table 1 provides a profile of the respondents who formed part of the study’ sample.

Table 1. Sample’s respondent profile

| | Frequency | Percentage (%) | | Frequency | Percentage (%) |
|---------------------|-----------|----------------|----------------------|-----------|----------------|
| Gender | | | Home language | | |
| Female | 309 | 55 | Afrikaans | 45 | 8 |
| Male | 255 | 45 | English | 53 | 9 |
| Age | | | Ndebele | 6 | 1 |
| 18 | 5 | 1 | Xhosa | 45 | 8 |
| 19 | 62 | 11 | Zulu | 98 | 17 |
| 20 | 151 | 27 | Northern Sotho | 46 | 8 |
| 21 | 143 | 25 | Southern Sotho | 121 | 22 |
| 22 | 92 | 16 | Tswana | 59 | 11 |
| 23 | 53 | 9 | Swati | 30 | 5 |
| 24 | 58 | 10 | Venda | 25 | 4 |
| Universities | | | Tsonga | 36 | 6 |
| Traditional | 196 | 35 | | | |
| UoT | 186 | 33 | | | |
| Comprehensive | 182 | 32 | | | |

The information laid out in Table 1 indicates that each of South Africa’s three main types of universities, each of the country’s 11 official languages and each of the seven age categories set out in the target population description were represented in the sample data. Slightly more female

than male respondents participated in the study and the majority of the respondents fell into the 20- and 21-year old categories (52%) and ticked Southern Sotho (22%) as their home language.

Following the computation of frequencies and percentages for sample description purposes, a principal component analysis was conducted applying varimax rotation to check for cross-loading items and for any items loading on a factor not in line with the literature. A Kaiser-Meyer-Olkin (KMO) of 0.785 and Bartlett's Test of Sphericity value of χ^2 3829.677, df 153, $p \leq 0.01$ confirmed that the data set was appropriate for principal component analysis (Pallant, 2020). Table 2 presents the rotated components, communalities, eigenvalues and percentage of variance extracted values.

Table 2: Rotated components and communalities

| Items | Factors | | | | | Communalities |
|-------------------------------|---------|-------|-------|-------|-------|---------------|
| | 1 | 2 | 3 | 4 | 5 | |
| MV1 | | | | .718 | | .567 |

MV: materialistic values; OGC: openness to global culture; COS: cosmopolitanism; EWM: exposure to Western media; EGB: exposure to global brand advertising

The results set out in Table 2 indicate that five components were extracted that explained 66.73 of the total variance. No items cross-loaded and all items loaded as per the literature. All communality values were above 0.40, thereby indicating that each of the items relate adequately to the other items in their respective component (Costello & Osborne, 2005). Furthermore, all loadings were above 0.50, signifying both statistical and practical significance (Hair *et al.*, 2019). Therefore, the underlying factor structure of five components reported in Table 2 is consistent with the literature; that is, consistent with the prior criterion approach followed in this study.

Once the structural integrity of the components solution had been established, confirmatory factor analysis was carried out in AMOS using the maximum likelihood method. This confirmatory factor analysis included measures of internal-consistency (α) and composite reliability (CR), measures of convergent and discriminant validity and model fit index assessment.

Reliability requires Cronbach α and CR values of 0.70 and above (Hair *et al.*, 2019), convergent validity necessitates CR values of 0.70 and above, together with standardised loading estimates and average variance extracted values (AVEs) of 0.50 and above, and discriminant validity calls for the square root of those AVE values (\sqrt{AVE}) to exceed their relevant correlation coefficients

(Fornell & Larcker, 1981). Given the salience of establishing discriminant validity when dealing with multi-variate statistical analysis, this study also included the computation of the heterotrait-monotrait (HTMT) correlation ratios between the latent factors, where values below 0.85 provide an additional indication of discriminant validity (Franke & Sarstedt, 2019). The measurement model specified for testing comprised the five latent factors of materialistic values (three indicators), openness to global culture (five indicators), cosmopolitanism (four indicators), exposure to Western media (three indicators) and exposure to global brand advertising (three indicators).

With the loading of the first indicator of each of the five latent factors set at 1.0, this equated to 189 distinct sample moments, 64 distinct parameters to be estimated and 125 degrees of freedom (df) based on an over-identified model and a chi-square value of 345.285, with a probability level equal to 0.000. The chi-square value returned by AMOS suggested poor model fit. However, this statistic is ill-famed for being susceptible to larger sample sizes (Byrne, 2010). As a result, the study considered other model fit indices. These indices included the normed fit index (NFI), the Tucker-Lewis index (TLI), the comparative-fit index (CFI), the standardised root mean square residual (SRMR) and the root mean square error of approximation (RMSEA). Acceptable model fit requires NFI, TLI and CFI values above 0.90, along with SRMR and RMSEA values below 0.08 (Malhotra, 2020).

Table 3 outlines the standardised loading estimates, error variance estimates, Cronbach α , CR, AVE, $\sqrt{\text{AVE}}$ values, correlation coefficients and HTMT ratios.

Table 3: Standardised loading estimates, error variance estimates, α , CR, AVE, $\sqrt{\text{AVE}}$ values, correlation coefficients and HTMT ratios

MV: materialistic values; OGC: openness to global culture; COS: cosmopolitanism; EWM: exposure to Western media; EGB: exposure to global brand advertising

The measurement model estimates depicted in Table 3 indicate evidence of composite and internal-consistency reliability, with all Cronbach *a* and CR values exceeding 0.70 (Hair *et al.*, 2019). These CR values, along with all standardised loading estimates and computed AVE values exceeding 0.50 confirm convergent validity. The discriminant validity of the latent factors in the measurement model is confirmed given that each computed $\sqrt{\text{AVE}}$ value exceeds its relevant correlation coefficients (Fornell & Larcker, 1981) and that all HTMT ratios are lower than 0.85 (Franke & Sarstedt, 2019). The NFI of 0.911, TLI of 0.928, CFI of 0.941, SRMR of 0.049 and RMSEA of 0.056 all infer acceptable model fit (Malhotra, 2020).

Therefore, the findings of the confirmatory analysis affirm that the influence of global consumer acculturation forces on Generation Y students' materialistic tendencies is a five-factor model comprising materialistic values, openness to global culture, cosmopolitanism, exposure to Western media and exposure to global brand advertising that presents as reliable and valid, and has acceptable model fit.

Before conducting the path analysis, the descriptive statistics were computed, together with a one sample t-test in order to determine the extent to which Generation Y students exhibit materialistic values and are open to the global culture, cosmopolitan, and are exposed to Western mass-media and global brand advertising. Descriptive statistics computed included means and standard deviations. For the one sample t-test, the expected mean was set at 3.5. These results of these are presented in Table 4.

Table 4: Descriptive statistics, t-statistics and *p*-values

| Latent factors | Means | Standard deviations | t-statistics | <i>p</i> -values |
|--------------------------------------|-------|---------------------|--------------|------------------|
| Materialistic values | 4.154 | 1.25480 | 38.733 | 0.000 |
| Openness to global culture | 4.181 | 1.02018 | 22.071 | 0.000 |
| Cosmopolitanism | 4.907 | 0.86291 | 37.215 | 0.000 |
| Exposure to Western media | 4.554 | 1.13453 | 15.849 | 0.000 |
| Exposure to global brand advertising | 4.913 | 0.90141 | 12.371 | 0.000 |

*Significant at $p \leq 0.01$

The t-statistics computed using the one sample t-test and their related *p*-values presented in Table 4 indicate that responses recorded on the six-point Likert-type scale were all significantly ($p \leq 0.1$) above the set expected mean of 3.5 and, therefore, in the agreement portion of the scale. The highest mean recorded was for exposure to global brand advertising (mean = 4.913), which is not surprising given the extensive number of advertisements, including advertisements for global brands that Generation Y consumers confront daily, not only through traditional media but now also through online social media platforms (Fallon, 2021). The next highest mean was recorded for cosmopolitanism (mean = 4.907). Pichler (2011) explains that higher levels of cosmopolitanism are linked to younger, better educated individuals who reside in multi-cultural societies, which explains the high mean recorded here for South African Generation Y university students. The next highest mean was recorded on the exposure to Western media factor (mean = 4.554). This

high mean is likely the result of the extent of Western-generated, especially Hollywood-generated content on popular South African entertainment platforms such as DStv, ShowMax and Netflix (Mwangi, 2020), as well as the amount of Hollywood celebrity gossip reported on in locally-available magazines. With Cohn’s d-values ranging between 0.929 and 1.631 (large effect size), exposure to global brand advertising, cosmopolitanism and exposure to Western media, were all also practically significant (Cohen, 1992). The two lowest means were recorded for openness to the global culture (mean = 4.181) and materialistic values (mean = 4.154). However, these means were still statistically significant ($p \leq 0.1$) and practically significant, with a computed Cohn’s d of 0.667 (medium effect size) for openness to the global culture and 0.521 (medium effect size) for materialistic values (Cohen, 1992). The statistically and practically significant mean for materialism values is in line with the findings of Cleveland *et al.* (2009), who indicate that younger individuals are more prone to materialism tendencies than older individuals. Taken together, these results suggest that Generation Y students in South Africa have materialistic values and are cosmopolitan, open to the global culture and are exposed to Western mass-media, as well as global brand advertising. In a study on young Nigerian consumers in Lagos, Lysonski and Durvasula (2013) also recorded high means for cosmopolitanism, exposure to global brand advertising, cosmopolitanism and exposure to Western media and lower means for openness to the global culture and materialistic values. However, in contrast to the findings of this study, the means they recorded for openness to the global culture and materialistic values were statistically and, obviously practically, non-significant.

Path analysis then ensued to address the primary aim of this study, which was to determine whether the forces of global consumer acculturation contribute to materialistic inclinations amongst Generation Y students in South Africa. The un-standardised and standardised regression estimates, together with the standard errors and p -values produced by AMOS are reported in Table 5.

Table 5.: Path analysis results

| Latent factors | Un-standardised β | Standardised β | SE | p |
|---|-------------------------|----------------------|-------|--------|
| Openness to global culture \rightarrow Materialistic values | 0.399 | 0.282 | 0.086 | 0.000* |
| Cosmopolitanism \rightarrow Materialistic values | -0.061 | -0.045 | 0.069 | 0.377 |
| Exposure to Western media \rightarrow Materialistic values | 0.027 | 0.028 | 0.054 | 0.623 |
| Exposure to global brand advertising \rightarrow Materialistic values | -0.058 | -0.034 | 0.098 | 0.558 |

*Significant at $p \leq 0.01$

As is evident in Table 5, the only global acculturation force to have a statistically significant positive influence of Generation Y students’ materialistic values was openness to the global culture ($\beta = 0.28$, $p = 0.00 < 0.01$). In practical terms, with a Cohen’s f^2 of 0.085 ($R^2/1-R^2$) this would constitute a small-medium effect (Cohen, 1992). Whilst exposure to Western media was a positive predictor of their materialistic values, that influence was statistically non-significant ($\beta = 0.028$, $p = 0.62 > 0.01$). Both exposure to global brand advertising ($\beta = -0.034$, $p = 0.56 > 0.01$) and cosmopolitanism ($\beta = 0.045$, $p = 0.37 > 0.01$) had a negative but non-significant influence on Generation Y students’ materialistic values. While these findings are contrary to the aggregate of the eight country results reported by Cleveland *et al.* (2021), they are similar to some of their individual country findings. These findings are similar to those of Lysonski and Durvasula’s (2013) Nigerian young consumer sample in terms of openness to the global culture being a

significant predictor of materialistic values and exposure to global brand advertising having a non-significant influence on those values. However, unlike the current study, the Nigerian study also found exposure to Western media to have a statistical significant influence on those consumers' materialistic values. Interestingly, the results of the current study almost mirror those of Gonzalez-Fuentes (2019), who found that openness to the global consumer culture was the only positive and only statistically significant predictor of materialistic values in his USA consumer sample and the only positive but non-significant predictor of those values in his Japanese consumer sample. These results are depicted visually in Figure 1.

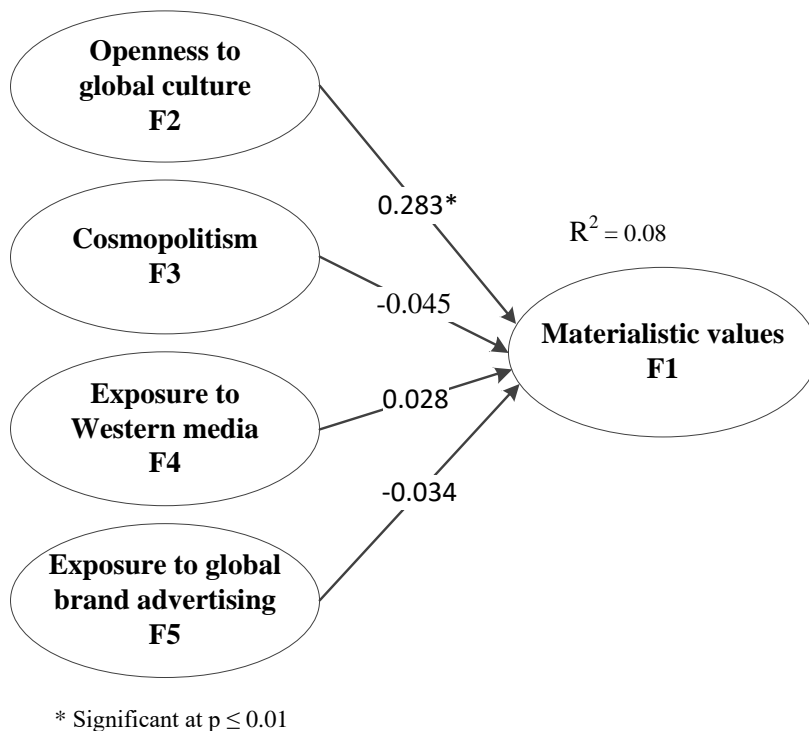

Figure 1: Structural model

As shown in Figure 1, with a squared multiple correlation of $R^2 = 0.08$ the global acculturation forces explain a negligible 8 percent of the variance in Generation Y students' materialistic values in South Africa. In terms of the model fit indices, this structural model also exhibited acceptable model fit with NFI of 0.911, TLI of 0.928, CFI of 0.941, SRMR of 0.049 and RMSEA of 0.056 (Malhotra, 2020).

The results of the two independent samples t-test conducted to ascertain if there were any significant differences between male and female respondents are reported in Table 6.

Table 6: Gender differences

| Latent factors | Means Males | Means Females | t-statistics | p-values |
|--------------------------------------|-------------|---------------|--------------|----------|
| Materialistic values | 4.203 | 4.113 | 0.841 | 0.400 |
| Openness to global culture | 4.053 | 4.286 | -2.712 | 0.007* |
| Cosmopolitanism | 4.854 | 4.952 | -1.330 | 0.184 |
| Exposure to Western media | 4.404 | 4.679 | -2.879 | 0.004* |
| Exposure to global brand advertising | 4.716 | 5.074 | -4.686 | 0.000* |

*Significant at $p \leq 0.01$

As presented in Table 6, while a higher mean was recorded for males on the materialistic factor, higher means were recorded for females on each of the global consumer acculturation factors. There were statistically significant differences between male and female sample participants on three of the five factors, namely openness to the global culture ($p = 0.007 < 0.01$), exposure to Western media ($p = 0.004 < 0.01$) and exposure to global brand advertising ($p = 0.000 < 0.01$). In each of these cases, higher means were recorded for the female participants. In terms of the four global acculturation latent factors, these findings echo those of Czarnecka *et al.* (2020), who also concluded that females are more acculturated to the global consumer culture than their male counterparts. Only a slightly higher mean was recorded for males on the materialistic values factor; however, this is in line with the findings of Cleveland *et al.* (2009) who also indicate that, overall, males exhibit higher materialistic values than their female counterparts. The latent factors where a statistical significant difference occurred were also practically significant; however, it is worth noting that with Cohn's d-values ranging from -0.229 to -0.405, the effects are only small (Cohen, 1992).

5. CONCLUSION

This study endeavoured to determine whether global consumer acculturation forces drive the materialistic values of Generation Y students in the context of the emerging market of South Africa. The evidence in the sample indicates that Generation Y university students in South Africa exhibit significant materialistic values and identify strongly with the global consumer culture. Furthermore, while males scored a non-significantly higher mean than female respondents on the materialism value factor, females scored higher on each of the global consumer acculturation forces, and significantly so on their openness to the global culture, exposure to Western media and exposure to global brand advertising. Despite the high mean scores recorded for materialistic values and each of the global consumer acculturation forces, the results of the path analysis indicate that only openness to the global consumer culture has a significant influence on those values, and a mere small-medium effect at that. Whilst this does not absolve globalisation forces, including Western media and global marketing efforts of playing a role in the spread of the consumer culture, it does show that the relationship is not as straight forward as sometimes portrayed. With the convergence of technology, media and financial markets, it is only natural that modernism will spread across the globe. This is not necessarily something evil and inherently materialistic as modernisation often leads to improved living standards. Marketers for their part, including marketers in multi-national organisations are guided by the principles of the marketing concept, particularly the principle of being customer oriented, which involves effectively satisfying consumer needs, including aspirations built on the knowledge of products and services available in more developed economies. Such aspirations do not necessarily translate into the avaricious pursuit of material possessions, as indicated by the results of this study. This study was cross-sectional in nature and, as such, provides only a snapshot in time. Furthermore, a non-probability sampling method was applied to gather the data, which places certain limitations on the extent to which the findings may be generalised to the target population. Moreover, the study only considered the influence of these global consumer acculturation forces on materialism, even though there is certainly scope for future research into their influence on Generation Y consumers' ethnocentrism towards South African made products and services.

THE CONNECTION BETWEEN EMPLOYEE MOTIVATION AND SUPPLY CHAIN MANAGEMENT SUCCESS IN THE MINING INDUSTRY

E.T. Mukansi

Private Researcher, South Africa

H.M. Dunga

Vaal University of Technology, Gauteng, South Africa

ABSTRACT

The productivity of employees in an organisation is regarded as a crucial component. To establish fruitful gains, there should exist some aspect of reciprocal effect between the employer and employee where both parties adhere to their roles and duties. From the employee's perspective, much is attributed towards the source of motivation and support provided by the employer, which gives them the courage to effectively carry out their duties. This paper investigated the factors contributing to employee motivation and supply chain success in the Palabora copper Mine, specifically the UMM contracting services company. To achieve an appropriate and well-informed outcome, the study collected data from 30 employees on the topic in question from a group of supply chain professionals and general staff within UMM contracting services. The paper employed a quantitative method using a questionnaire for data collection. A five-point Likert scale was employed, adopted from Fourie's (1989) motivation questionnaire on workplace motivations, which were identified as monetary aspects, employee development, reward recognition, interpersonal relations, and staff supervision. The results indicated that 90 percent of the population perceived that monetary aspects were the most prominent aspect motivating them to stay on the job. According to gender, the company is mostly dominated by males.

Keywords: Employee motivation, supply chain success, mining industry, Likert scale

1. INTRODUCTION

Employee motivation is crucial and has a huge influence on the overall performance in the mining industry for enhanced productivity. Top management plays a key role in ensuring that strategic decisions in the supply chain are executed. However, the employee's involvement in executing the strategic decisions in an organisation is vital as they drive those strategic decisions at operational level (Boundreau and Robey 2015:251). However, Dallas and Martin (2007:64) illustrate that employee's need development and training to drive strategic decisions from an operational level point of view. This is further argued by Kreisman (2002) that the greatest valued resources an organisation can have should incorporate consistent workers that are capable, fully committed, as well as efficient. The mining industry is a major contributor to South Africa's economic development and continues to play a significant role in empowering local communities through employment opportunities and development. The industry is, however, known for its hazardous working conditions that lead to chronic diseases, injuries, and deaths. The extreme working conditions tend to stifle the interest from females to enter this sector. However, as badly reputed, and hazardous as the industry is, it continues to attract new talent and retain its existing workforce.

Dessler (2003) contends that the lack of motivational tools or programmes to boost the morale of the workforce is one component that drives out employees from the hazardous sector and the industry, thus impacting on the sustainability of the industry. Armstrong (2010) suggests that if companies were to take into consideration what is required of them to motivate their team, in order to realise consistent outstanding results from the employees, which involves going as far as providing monetary rewards based on performance, it would help employees obtain the satisfaction and recognition for their work and motivate them to continue performing well by using incentives and rewards. Further, Bratton & Gold (2007) stipulate that rewards could be used attract but also retain the best qualified workers into the industry, attain organisational goals and generate more revenue. Caruth and Handlogten (2002) state that performance appraisals have been regarded as early pioneers of motivating employees. Hafiza et al. (2011) suggests that offering insufficient supporting programmes to the workforce, ultimately, has a negative impact on overall performance. (Carragher, Gibbson & Buckley, 2006), argues that there are various methodologies for encouraging team morale in the organisation, ranging from acknowledging the individual's accomplishments through praise and assign responsibility with benefits for outstanding outcome. Torrington, Hall and Taylor (2008) further contend that best performance in an organisation can be achieved in making sure of proving job security measures to all employees of which one aspect could be absorbing its personnel on a permanent job basis. In so doing individual employees can thus acquire goods that satisfy their personal needs such as a decent house, vehicle and assets. It has been argued that high levels of motivation lead to high levels of input from employees in their duties, thus maximising the organisational output (Bhattacharyya, 2007; Lawler 2003). Further Dougherty and Dreher (2002) argued that the way an organisation manages its staff influences its capacity to build and retain greater market share against their competition.

The mining industry plays a crucial part in contributing to the country's economic growth. It has been reported that the mining sector is largely male dominated, which could be attributed to severe and hazardous working conditions that otherwise scare females to enter the sector. Although mining professions often provide salary and individual fulfilment, they may also present dangerous threats to one's health & welfare. As a result, this paper intended to find the most effective motivator among supply chain employees within the Palabora Copper Mine in Limpopo province, which will ensure that miners have safe working conditions to achieve their objectives. The study found a lot of gaps in the literature on this subject; there have not been many studies done focusing on the motivation of employees in the mining industry, presenting a need for further research. This study will address the gap by determining what truly motivates workers already in the mining business. Despite health and safety measures established to make mining a safe working environment, it has also been reported that there have been so many incidents in the industry, such as the incident that occurred in the Palabora Mining Company in 2016, where a conveyor belt caught fire with three employees succumbing to the incident. However, most of the reports are anecdotal and are not backed by research findings.

The goal of this investigation is to quantitatively uncover the connection between employee motivation and supply chain success in the mining sector through looking at tools and strategies used by organisations within the sector to align the two aspects aimed at a successful supply chain.

2. LITERATURE REVIEW

This section reflects on the literature behind the topic in study, as stipulated by Brown, Squire and Blackmon, (2017) Fink (2018) & Aveyard (2010) of the importance of a literature review. Based on a study of previous studies, a conceptual framework is constructed in this research article and implications for human resource departments are presented.

The study published by Sekaran (2002) emphasised the significance of motivation in an organisation and demonstrated the need for effective inspiration to staff, the presumption that effective organisations would be those who best utilise their human resource as they would any other resource. The Hawthorne investigations sparked the human relations approach to management, in which senior management prioritise the interests and encouragement of their employees (Bedeian, 1993). Individuals, whether in office or commercial businesses, are viewed as one of the crucial variables for the accomplishment of business objectives, according to Golzadeh's (2001) research on elements impacting worker engagement. As a result, motivating elements amongst workforce must be identified to improve efficiency and production and then efforts must be made by the company to meet those demands of workers. As a result, motivation's comprehension and applicability are reliant on the information and abilities required to do so. In general, all managers must be aware of motivation as the source of encouragement leading to employee behaviours carried out in the company. The study on motivation provides solutions to issues about human behaviour, such as why do people work in organisations? Why some individuals are active, and others are not? What are the factors that influence job desire or boredom? These and other issues are relevant to the topic of motivation and the solutions may be sought throughout the context of employee motivation and motives. As a result, by mastering how to encourage people, managers may easily take some steps to achieve business objectives in collaboration with personnel while also effectively performing their primary tasks.

It is critical to increase employee satisfaction and willingness to participate in their tasks, as well as the attainment of corporate objectives (Abzare, 2010). It is advised to first develop long-term morale for employees in an organisation to succeed in today's harsh employment climate. On the research of the effect of supply chain performance and motivation on employee performance, Sabir (2020) argues that motivation is crucial in determining an organisation's objective achievement. With rewards, perseverance and team objectives, motivation supports behaviour for voluntarily tasks (Lehman & Creener, 2002). Several research in the field of organisational behaviour shows that employee encouragement has a beneficial impact on performance (Mathis & Jackson, 2010)

According to Baron (1983), not only could motivation impact performance, but performance too could inspire enthusiasm provided it is accompanied with incentives. Carraher (2006) argues that an appropriate and efficient incentive program should be in place to keep top performers in companies and that the incentive must also be linked to overall output. As a result, Baron (1983) finds that creating total compensation programs that focus on recognition and rewards policies might help businesses. Armstrong (2010) claims that a motivation approach is required for carrying out everyday duties and encouraging people toward shared business objectives. However, it requires not only the selection or collection of statements that represent the goal, but mostly the application of skills that achieve the goal (Palmer, 2005). The inspiration progression obeys defined company procedures that, as a result, should be assessed and maintained repeatedly to preserve their effectiveness (Green, 2000).

2.1 Employee motivation

Employee motivation is defined by Robbins (1993) as “the willingness to exert high levels of effort toward organisational goals, conditioned by the effort's ability to satisfy some individual need”, however, George and Sabapathy (2011) define it as “an action that stimulates an employee to take a course of action, which will lead to the achievement of some goal or to the satisfaction of some individual need”. Motivation is described by Robbins and Judge (2008) as the mechanisms that account for an individual's intensity, direction and persistence of effort toward realising goal. Page (2008) defines motivation as the process that accounts for an individual's intensity, direction and persistence of effort toward achieving a goal in his essay on non-monetary rewards in the workplace. Motivation, according to Cole (1996), is simply what motivates a person to work in a certain way and with a certain level of effort, which is internally produced, driven to attain a goal or take a specific course of action. Ramlall (2004) concludes the definition, articulating that employees that are highly driven concentrate their efforts on reaching specified objectives. As a result, it is the role of the organisation to drive individuals to perform their best work and further employees that are motivated are far less likely to call in ill, are more productive and can communicate effectively with customers and co-workers.

It is crucial, therefore, to understand the difference between internal and extrinsic drive. Simply said, intrinsic motivation stems from within, the pleasure derived from a work, the contentment derived from a good performance and the drive to succeed are all examples of intrinsic motivation. Extrinsic motivation, on the other hand, is triggered by external circumstances such as a bonus or some other type of reward. Extrinsic drive can also stem from avoiding punishment or a negative consequence. Motivation has a favourable impact on individual and group performance, which in turn has an impact on an organisation's success (Risambessy et al., 2012). Companies have recently recognised the importance of highly motivated employees on an organisation's overall success in reaching its goals and operating efficiently. As a result, heavy industrial sectors such as mining have included motivation strategies into their decision-making so that employees' inspirations are satisfied and that they are able to do their responsibilities effectively, resulting in the success of the organisation's supply chain.

2.2 Supply chain management practices

Supply chain management practices, according to Qusheri (2014), are a comprehensive collection of measures taken by firms to increase the efficiency of their internal supply chain. Supply chain management methods, according to Pettit and Beresford (2009), are strategies to manage the integration and coordination of supply, demand, and relationships to fulfil customers in an effective and profitable manner. The study agrees with Brown, Squire and Blackmon, (2017), who defined SCM practices as a collection of actions carried out in an organisation to enhance successful supply chain management. Employee motivating approaches are important in our research since it emphasises the effective application of good supply chain procedures, the ultimate objective of which is to make the company more efficient and lucrative in order to sustain market dominance in the sector. As a result, the far more essential aspects that drive the performance of the mining sector supply chain operations are the implementation of current employee methods and logistics technology, as well as an education campaign on staff motivation and reaction (Zhou, 2011).

In order to provide personnel motivation techniques that are appropriate for both men and women in the mining industry, it is necessary to first understand the distinctiveness of difficulties, which both male and females encounter in the sector, such that the encouragement or reward provided is appropriate for uniformity. As a result, when planning a motivation and incentive activity in any mining sector, the dynamics of the society within the company must be understood in order for the motivational techniques used to be effective, as men and women have different needs, which are influenced by different aspects. The atmosphere, business circumstances, beliefs, behaviours and personnel impressions of the firms in which they work are all shaped by supply chain performance. The success of an organisation's supply chain is a predictive factor that may boost productivity, accountability and effectiveness Haddouch, 2019 and Ernawan, 2011 emphasises the importance of establishing a workplace structure that fosters production efficiency and enhances employee performance. Following best practices, the organisation can recognise weaknesses in the current framework and approaches through collaborative efforts and interaction with its workforce; therefore, is able to correct and incorporate programs that would see workers being highly motivated and producing significant outcomes for the company, resulting in supply chain management success. In the end, employee morale will be boosted by factors such as fair compensation, job satisfaction and a safe and suitable work environment, which will ultimately help the company accomplish its goals. The next section addresses the methodology employed in the study.

3. METHODOLOGY

This section outlines the methodology for the paper.

3.1 Research design

The study used a questionnaire using a validated five-point Likert scale adopted from Fourie's (1989) motivation questionnaire on workplace motivation. The response options examine the effectiveness of motivational programs that each employee witnessed in the firm. The choice of the scale was based on the fact that it is easier to quantify the responses and compile statistical data and figures.

3.2 Sampling method and Research instrument

The study used a questionnaire consisting of 30 closed-ended questions, which were divided into two parts. The first part examined the socio-demographic and qualification characteristics of the employees in the UMM Contracting services. The survey included basic data on respondents concerning their age, gender, number of years of service in the business, completed education and job positions. The questionnaire was administered using a soft copy in English, which took approximately 15 minutes to complete. The target study population from the questionnaire was the mining workers particularly from the UMM contracting services, Phalaborwa, South Africa. Workers were sent information about the study and the copy of questionnaire survey to be filled. Participation in the study was voluntary and responses were kept anonymous and only used for academic purposes.

3.4 Data collection and data analysis

Due to the time the survey was conducted, to follow the COVID-19 protocols, it was not possible to administer the questionnaires face-to-face, rather a soft copy was sent through emails to 40 randomly selected respondents who were best fit for the study. The responses were sent back through the same system. After data cleaning, only 30 questionnaires were found suitable to be used. The responses were inputted and analysed using a Statistical Package for Social Science (SPSS). Das and Kumar (2014) compliment the use of SPSS as it enables researchers to build and validate predictive models using advanced statistical procedures. The study follows a quantitative method, which is less time-consuming; hence, the use of questionnaires. The research data gathered for this study were coded in short phrases and cleansed using Excel spreadsheets to make it easier to enter the analysing software for further analysis. Descriptive analysis for personal and company information of the supply chain member firm managers was performed. The next section presents the results of the study.

4. RESULTS AND DISCUSSION

4.1 Gender

Figure 1 presents results of the gender demographics of the study, which shows that 73 percent of the respondents were males while 27 percent were females, it is thus noted that the company has more male workers than women. Results show that females continue to fall behind males in terms of presence in the mining sector, this could be attributed to the hazardous nature of the mining sector, which leads to women diverting from the industry. Subsequently, a smaller percentage of women occupy the top supply chain positions such as the supply chain managers, procurement, and logistics. The results are line with prior research, which claims that females make up roughly 5 percent of senior supply chain management jobs at large corporations (Eshkenazi 2014). Eshkenazi (2014) further links the female's shortage in the mining industry due to the nature of the environment and their experience. However, lately organisations are embracing the concept of diversity and doing away with old and discriminatory treatment against women attempting to tap into the sector.

Figure 1: Gender dynamics

4.2 Respondent age

Table 2 presents results of age distribution; it shows that the majority of UMM workers (53, 3%) are aged between 30 to 40 while 13.3% are aged between 20-30 and above. 23.3% of the sample respondents are aged between 40-50 and 10% are between 50-60 years. It means that in this company there are more young people (30-40 yrs) than old people, this could be because of the intensive work that old people may not be able to cope with. The employee income distribution is discussed in the next session.

Table 2: Age distribution of the study

| | | AGE | | | |
|-------|-------|-----------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Age | 20-30 | 4 | 13,3 | 13,3 | 13,3 |
| | 30-40 | 16 | 53,3 | 53,3 | 66,7 |
| | 40-50 | 7 | 23,3 | 23,3 | 90,0 |
| | 50-60 | 3 | 10,0 | 10,0 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

4.3 Respondent Income

Table 3 depicts the income distribution of UMM employees, with 63,3 percent earning between 20-40 thousand Rands monthly while 26,7 percent of respondents receive income between 40-60 thousand Rands, 6 percent of respondents get between 60-80 thousand with one person accounting for 3,3 percent of respondents receiving between 30-40 thousand, majority of respondent are in the category of 20-40 thousand Rands and looking at the amount it shows that it is quite reasonable amount that one would get. People working in the mining certainly get good money which lead to high employee motivation and thus able to produce outstanding performance and results for the organisation.

The salaries are satisfactory and competitive and serve as the motivational factor for enhanced performance and the willingness from respondents to stay within the mining industry until retirement. It is vital to note that when employees are well paid, they become extra motivated.

Table 3: Income distribution of population

| | | INCOME | | | |
|--------|-------|-----------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Income | 20-40 | 19 | 63,3 | 63,3 | 63,3 |
| | 30-40 | 1 | 3,3 | 3,3 | 66,7 |
| | 40-60 | 8 | 26,7 | 26,7 | 93,3 |
| | 60-80 | 2 | 6,7 | 6,7 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

4.4 Distribution of Race

Table 4 shows that most of UMM contracting services workers are black people accounting for 76.7 percent with most of them being less skilled workers (General miners and operators); followed by whites accounting for 20,0 percent and 3,3 percent coloureds. The high number of black workers in the industry can be seen as the results of the people who have been previously marginalised and had to resort to the labour-intensive work opportunities. The main reason why blacks might be dominating the UMM workforce could be the organisation practice of corporate social responsibility to empower and uplift local communities, which are mostly blacks.

Table 4: Race of study population

| | | RACE | | | |
|------|----------|-----------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Race | Black | 23 | 76,7 | 76,7 | 76,7 |
| | white | 6 | 20,0 | 20,0 | 96,7 |
| | Coloured | 1 | 3,3 | 3,3 | 100,0 |
| | Total | 30 | 100,0 | 100,0 | |

4.5 Position held

Table 5 shows the distribution of positions held in the company; it shows that the black majority are in the low position ranks (general miner and operators). The company is committed to advancing career growth of its workforce and this is evident with the organisation incorporating continuous development and training of personnel in order to escalate lower ranked employees into better ranks.

Table 5: Position of respondents

| | | Position held | | | |
|-----------|----------------|---------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Positions | General miner | 8 | 26,7 | 26,7 | 26,7 |
| | Operators | 8 | 26,7 | 26,7 | 53,3 |
| | Supervisors | 3 | 10,0 | 10,0 | 63,3 |
| | Superintendent | 2 | 6,7 | 6,7 | 70,0 |
| | Miner | 3 | 10,0 | 10,0 | 80,0 |
| | SCM | 4 | 13,3 | 13,3 | 93,3 |
| | Shift boss | 2 | 6,7 | 6,7 | 100,0 |
| | Total | 30 | 100,0 | 100,0 | |

4.6 Highest qualification

Table 6 shows that 46,7 percent, which represents the majority of study population (general miners, operators and supervisors in the company) have high school certificates or less, while 33,3 percent are diploma holders. 20,0 percent of the respondents are first degree holders. These findings show that the mining industry is mostly associated with manual labour-intensive duties that do not necessarily require high levels of qualification; hence, we see high numbers of employees with low education (46,7%). Employees grow in the industry through their experiences as we saw other individuals occupying high ranks such as supervisor and superintendent without having a matric. The next section discusses the number of years worked.

Table 6: Level of education

| | | HIGHEST QUALIFICATION | | | |
|-----------|--------------|-----------------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Education | Matric below | 14 | 46,7 | 46,7 | 46,7 |
| | Diploma | 10 | 33,3 | 33,3 | 80,0 |
| | 1st degree | 6 | 20,0 | 20,0 | 100,0 |
| | Total | 30 | 100,0 | 100,0 | |

4.7 Number of years worked

Table 7 shows the results on numbers of years worked in the company, its shows that most workers have worked for a long time in the mining sector with 57, 7 percent accounting for the longest time of between 9-15 years. This could be the reason they are earning more money because they have been in the company for so long. Regardless that they do not have a lot of skills in terms of qualification but because they have stayed in the company for a long time whereby, they have actually learnt a lot and mastered their work through the years, their salaries have been increasing.

Table 7: Experience of respondents

| | | NUMBER OF YEARS WORKED | | | |
|------------|---------|------------------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Experience | 0-5 | 5 | 16,7 | 16,7 | 16,7 |
| | 6 to 8 | 8 | 26,7 | 26,7 | 43,3 |
| | 9 to 15 | 17 | 56,7 | 56,7 | 100,0 |
| | Total | 30 | 100,0 | 100,0 | |

4.8 Income cross tabulation

It is evident from table 8 that those employees that have degrees are the ones that earn more money, which means the higher the qualification the more money you will get paid. Higher educational level and work experience has a significant role on the employee income. These findings are in line with Walker, Di Sisto and Mc Bain's (2008:82) prior research, which found that the amount of education and training had an impact on the compensation package, particularly in the mining business. Low ranked workers are rewarded with good salaries for the type of work that they do. These employees gain more experience from the duties they do over the years therefore their salaries increase over the years.

Table 8: Income across educational level

| | | HIGHEST QUALIFICATION * INCOME CROSS-TABULATION | | | | |
|--------------|--------------------------------|---|--------|--------|--------|--------|
| | | INCOME | | | | Total |
| | | 20-40 | 30-40 | 40-60 | 60-80 | |
| Matric | Count | 12 | 0 | 2 | 0 | 14 |
| | % within HIGHEST QUALIFICATION | 85,7% | 0,0% | 14,3% | 0,0% | 100,0% |
| | % within INCOME | 63,2% | 0,0% | 25,0% | 0,0% | 46,7% |
| | % of Total | 40,0% | 0,0% | 6,7% | 0,0% | 46,7% |
| Diploma | Count | 6 | 0 | 4 | 0 | 10 |
| | % within HIGHEST QUALIFICATION | 60,0% | 0,0% | 40,0% | 0,0% | 100,0% |
| | % within INCOME | 31,6% | 0,0% | 50,0% | 0,0% | 33,3% |
| | % of Total | 20,0% | 0,0% | 13,3% | 0,0% | 33,3% |
| First degree | Count | 1 | 1 | 2 | 2 | 6 |
| | % within HIGHEST QUALIFICATION | 16,7% | 16,7% | 33,3% | 33,3% | 100,0% |
| | % within INCOME | 5,3% | 100,0% | 25,0% | 100,0% | 20,0% |
| | % of Total | 3,3% | 3,3% | 6,7% | 6,7% | 20,0% |
| Total | Count | 19 | 1 | 8 | 2 | 30 |
| | % within HIGHEST QUALIFICATION | 63,3% | 3,3% | 26,7% | 6,7% | 100,0% |
| | % within INCOME | 100,0% | 100,0% | 100,0% | 100,0% | 100,0% |
| | % of Total | 63,3% | 3,3% | 26,7% | 6,7% | 100,0% |

4.9 Monetary aspect

Table 9 shows that most of the study population (80%) were satisfied with their salaries and other benefits within the organisation, which was mostly dominated by employees with low educational levels and thus find their remuneration packages fair and satisfactory and this is no surprise considering their educational level and the salaries they receive, with 63.3 percent of respondents ranging between 20-40 thousand rand. While 20 percent showed dissatisfaction with regard to the monetary aspects offered by the company and looking at the sample population, these are people with tertiary qualification and considering the investment they have made in acquiring these qualifications they surely believe they deserve better packages for their knowledge and expertise, we can however note that some tertiary education holders are not employed in the department of their professions and thus the dissatisfaction with their remuneration.

Table 9: Monetary aspect category

| | | MONETARY | | | |
|-------------|----------|-----------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Respondents | 1 to 10 | 6 | 20,0 | 20,0 | 20,0 |
| | 11 to 20 | 24 | 80,0 | 80,0 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

4.10 Employee development

Table 10 indicates that 80 percent of the participants agree that they are motivated by the development of employees in the company with the majority of workers testifying that they are happy with their salaries. This can be true with over 56 percent of the participants salary ranging between 20-40 thousand rand per month and one has to take note that these are people with matric or below and it thus understandable. However, some respondents with diplomas and higher showed dissatisfaction with their salaries and were not merely motivated with the monetary benefits but it was rather the job that they were passionate about and hence their output would be positive because they are doing something they enjoy

Table 10: Employee development category

| | | EMPLOYEE DEVELOPMENT | | | |
|-------------|----------|----------------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Respondents | 1 to 10 | 6 | 20,0 | 20,0 | 20,0 |
| | 11 to 20 | 24 | 80,0 | 80,0 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

4.11 Interpersonal relationship

The majority of employees (96,7%) shown in table 11 attest that they enjoy a good relationship with their co-workers, which boosts their morale and are thus able to be effective in their tasks, leading to supply chain success. Almost 100 percent of the employees agreed that working in the mining industry is risky and mostly associated with labour-intensive activities; hence, it is male-dominated, although females are starting to enter the industry through non-labour-intensive ranks such as safety officers, finance, engineers and supply chain professionals.

Table 11: Interpersonal relationship category

| | | INTERPERSONAL RELATIONSHIP | | | |
|-------------|----------|----------------------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Respondents | 1 to 10 | 1 | 3,3 | 3,3 | 3,3 |
| | 11 to 20 | 29 | 96,7 | 96,7 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

4.12 Staff supervision

93,3 percent of the respondents presented in table 12 show that they are trusted with carrying out their duties with minimal supervision and this gives the employee confidence and are thus able to execute their tasks more effectively with less supervision. Less supervision applied on these employees could be attributed to that they have been in the industry for some time and that the majority have the experience to carry out tasks on their own. About 50 percent of the respondents say they are given chance to make decisions with over 92 percent of the respondents showing that their superiors listen to their suggestions and concerns and that goes to show the teamwork that exists within the organisation. About 45 percent expressed that the organisation is not loyal to

customers, it may be due to the organisation retrenching a lot of workers during the peak of COVID-19 in the country.

Table 12: Staff supervision category

| | | STAFF SUPERVISION | | | |
|-------------|----------|-------------------|---------|---------------|--------------------|
| | | Frequency | Percent | Valid Percent | Cumulative Percent |
| Respondents | 1 to 10 | 2 | 6,7 | 6,7 | 6,7 |
| | 11 to 20 | 28 | 93,3 | 93,3 | 100,0 |
| Total | | 30 | 100,0 | 100,0 | |

5. CONCLUSION

The scope of this research study covered UMM Contracting services at Palabora Copper mine in South Africa. The main aim of this research intended to address the connection between employee motivation and supply chain success in the mining industry and particularly the UMM Contracting services.

Based on the research objectives, a quantitative research methodology was adopted to capture the respondents' thoughts. The data were then analysed through a descriptive method using SPSS tool. The survey questions were structured in such a way that they would be able to answer the objectives of the study. Therefore, the objectives of effectiveness of motivation programs were answered through analysis of respondent's data, which shows that the majority are content with the existing motivation program applied in the organisation. The other objective was answered by the study's analysis, which shows the correlation between supply chain performance and employee motivation. Supply chain performance is enhanced when employees are highly motivated and thus organisation's need to ensure they have an effective approach to motivate their workers, leading to supply chain efficiency and throughput.

According to the study, UMM Contracting employees are driven by intrinsic and extrinsic factors. The biggest motivator for workers in the mine sector has been recognised as decent compensation. According to the research, the workers happiness results in improved performance. Organisations must establish strong initiatives and tools, which workers should adopt in order for all of them to be devoted to their jobs. Lawler (2003) stipulates that the way corporations treat their personnel determines their success and sustainability in the market as well as their public image. One of the concerns that came up was management disloyalty. The study also found that despite the risks involved in mine business, Palabora Copper maintains a good health and safety strategy, since min regulators mandates organisations to implement measures to avoid probable work health & safety violations.

The study concluded that treating employees' right and giving them satisfactory compensation led to enhanced supply chain performance as the employees act in the best interest of the organisation when they are happy, which results in a win-win situation for both parties

5.2 Recommendations

Employee productivity must be assessed on a periodic basis by Palabora Copper to address variables, which inspire employees. As a result, the company will be always aware of the employees' most important needs and thus will try to meet them for enhanced employee motivation. The workforce should be issued with surveys for their perceptions and recommendations on the strategies to implement.

Worker's safety and health concerns must be taken into account in the future, primarily for workers who are exposed to unsafe toxins and dangerous substances and several other elements that have been acknowledged as impacting employee performance and productivity.

Policy makers must incorporate females so that there can be equality in the organisation as it can be seen from the study population that the company is male-dominated.

This study is likely to make significant contributions towards the collection of studies about employee motivation in the mining segment. The research is also intended to assist mining businesses and governments in understanding the importance of employing methods such as employee motivation aimed at the attainment of supply chain management success in the mining business.

5.3 Limitations

First, the study was confined to the respondents only in the UMM Contracting services, in particular the Palabora Copper, South Africa; therefore, the findings addressed the company in study. The results would be more informative if data from other mining companies were collected, examined and compared.

Due to COVID-19 protocols, it was not possible to conduct in-person interviews; instead, emails and help from employees in the company to distribute the surveys were the solutions used.

CORPORATE SOCIAL RESPONSIBILITY AND CORPORATE IMAGE TOWARDS CUSTOMER REPURCHASE INTENTION: TESTIMONY FROM SOUTH AFRICA'S BANKING ENVIRONMENT

L.A. Masitenyane

Vaal University of Technology, Vanderbijlpark, Republic of South Africa

R.M. Shamhuyenhazva

Vaal University of Technology, Vanderbijlpark, Country Republic of South Africa

ABSTRACT

Given the importance of corporate social responsibility (CSR) and its effects on stakeholder behaviour. Literature review identified factors used to investigate the impact of CSR and corporate image on banking customers' repurchase intentions. This study investigates the influence of banking customer-perceived CSR initiatives on relationship quality and repurchase intention, moderated by corporate image. Preceding studies found significant associations between CSR initiatives and relationship quality; however, no study, particularly in South Africa's banking environment, examined effects of CSR initiatives on customers' repurchase intentions, moderated by corporate image. A framework was designed applying cross-sectional quantitative research using convenience sampling through a survey questionnaire. Only 551 valid questionnaires from banking customers in Gauteng province of South Africa were analysed. The Statistical Package for Social Science (SPSS) and the Analysis of Moment Structures (AMOS), 26.0 versions, were applied. The findings show significant relationships exist between CSR measures and the study constructs. Results indicate that the banks' CSR initiatives are supported as precursors of relationship quality towards customer repurchase intentions and CSR has an insignificant relationship with corporate image. It can, therefore, be concluded that direct effects of the bank's CSR initiatives on relationship quality lead to customer repurchase intentions. Accordingly, the bank and marketing managers can employ CSR initiatives to enhance customer support and repurchase intentions in the quest to meet stakeholder expectations. Moreover, service marketers must realise that customer-perceived CSR initiatives influence second-order constructs in the South African banking context.

Keywords: Banking sector; corporate social responsibility; corporate image; relationship quality; repurchase intention

1. INTRODUCTION

In today's socially mindful marketplace, corporate social responsibility (hereafter CSR) has developed to be a relevant research topic that has received widespread attention from various researchers (Servera-Francés & Piqueras-Tomás, 2019; Pérez & Rodríguez Del Bosque, 2015). Motilewa and Worlu (2015) state that CSR can be considered a management system that service providers can use to improve competitiveness and intensify customer gratification toward positive repurchase behaviour (Servera-Francés & Arteaga-Moreno, 2015). In other words, CSR initiatives stimulate stakeholder (customer) satisfaction leading to favourable repurchase actions. The extant literature offers evidence of the effects of CSR on customer behaviour from different approaches,

through an examination of various constructs such as loyalty (Rivera et al., 2019); image and reputation (Alvarado-Herrera et al., 2017); as well as corporate image and purchase intentions (Huang et al., 2014). The findings from these and many other studies conducted mostly in developed markets reveal dissimilar outcomes in favour of organisations that engage in CSR initiatives. Many of these studies investigated the significance of customer CSR perceptions relative to improved business corporate image (Kim et al., 2015). Very few investigations, especially from developing markets, examine the impact of CSR on service quality and customer satisfaction (Bello et al., 2020). According to the researchers' best knowledge, no study has empirically examined the proposed study constructs, particularly in the South African banking environment as a developing market. Thus, in an attempt to mitigate this research gap, this study aims to investigate the influence of CSR initiatives on customer repurchase intentions in the banking service environment of a developing market. Pather (2016) denotes repurchase intention as customer behaviour resulting from their previous satisfying purchasing encounter of the same product or services, from the same organisation being an envisaged outcome for organisations that could lead to increased business profits (Blut, Frennea, Mittal & Mothersbaugh, 2015). The research question guiding this study is: What are the effects of the bank's CSR initiatives on relationship quality and corporate image, leading to customer repurchase intention from South Africa's banking service context?

2. LITERATURE REVIEW

2.1 CSR and the South African banking environment

Servera-Francés and Piqueras-Tomás (2019) state that CSR is an important marketing tool centred around available information related to organisational economic, legal, ethical, social and environmental obligations, which influences customer behavioural reactions. For example, a bank that offers customers free training on cash and money management tutorials to retain the upskilled client base, can suggest that the bank is truly committed to its responsibilities of accountability and engagement relating to social initiatives. In South Africa, commercial and private banks operate under the guidelines of the South African Reserve Bank, which ensures price stability is upheld to promote viable economic growth and an inspiring domestic banking system in the country (South African Reserve Bank, 2015). All the banks involved in this study are categorised as mutual and liquidation financial service providers, presented in alphabetical order as ABSA Bank, FirstRand Bank Limited (FNB), Investec, Nedbank Limited and Standard Bank of South Africa Limited (South African Reserve Bank, 2020). Lately, these financial institutions, including others, have promoted socially and environmentally responsible lending and investment practices that enhance their business image (Businessstech, 2020).

2.2 CSR measures

This study uses a more broadly used classification of CSR proposed by Carroll (1979; 1991), who explains CSR as a four-level model. From Carroll's (1991) work, the CSR pyramid consisting of four measures, namely ethical, legal, economical and philanthropic measures are considered fit to deal with the organisation's societal obligations (Maignan, 2001). The ethical measure deals with the managerial responsibilities aimed at ensuring honest operations and keeping up with moral societal norms (Galbreath, 2010). The legal measure oversees that organisational practices are

acceptable and protect the rule of law by implementing legal policies and obligations (Carroll, 1991). Economic measure relates to products and services presented to meet the market needs and requirements with the aim to gain profits (Ramasamy & Yeung, 2009), although not taking stakeholder interests to heart (Barnett, 2007). Philanthropic measure is regarded as commitment with the intent to engage in various social initiatives relating to community welfare, educational activities and the sporting fraternity (Godfrey, 2009). However, such initiatives can only be realised through the support of ethical and philanthropic measures (Yang et al., 2019). Figure 1 illustrates Carroll's (1991) four measures of CSR as a pyramid.

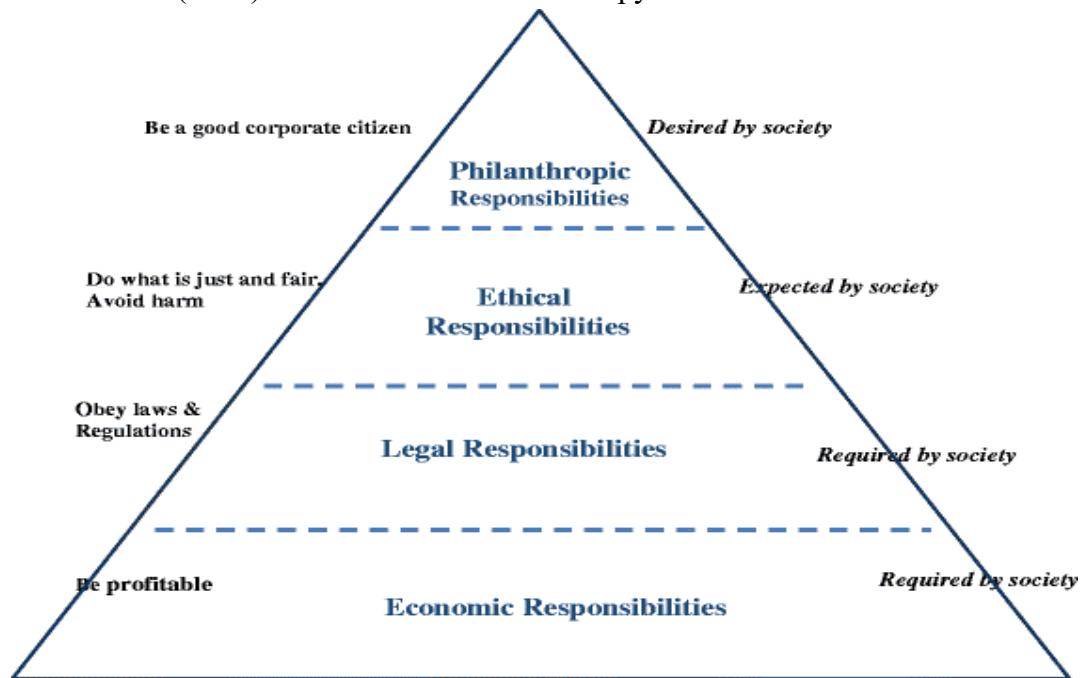

Figure 1: Carroll's (1991:39) pyramid of CSR

The economic responsibilities represent the basis of accountability upon which other measures are built. The legal measure ratifies that the organisations are legally held liable to fulfil their economic responsibilities, without contravening the laws of the territory in which they operate. Ramasamy and Yeung (2009) state that these may comprise tax laws, labour laws as well as health and safety rules. Ethical responsibilities represent undertakings associated with morality and social norms such as dealing with legal standards and obeying the laws concerning the hiring and firing of employees (Galbreath, 2010). The philanthropic responsibilities represent the organisation's humanitarian activities executed to deal with the ethical, social and charitable practices aimed at the well-being of communities in which the organisation is operating (Carroll, 1991).

2.3 Relationship quality

Relationship quality originates from relationship marketing theory and research, wherein, it aims to strengthen the existing customer relations and transform them into long-term business associations (Lin, 2013). De Canniere, De Pelsmacker and Geuens (2010) signify that relationship quality can be regarded as a customer's view of the association with a service provider concerning how well the partnership meets their expectations. Accordingly, the service provider's degree of relationship quality signifies the customer's inclination and interest in retaining and growing their relationship (Adjei et al., 2009). Thus, it must be borne in mind that customers who do not feel the

presence of a decent relational bond with their service provider, will remain indifferent resulting in deficient returns on investment due to declining customer support (Mende et al., 2013).

2.4 Corporate image

Corporate image is explicated as an overall feeling in the customer's mind following cumulative beliefs, views and encounters accumulated in memory turned into meaning and retrieved to form a mental picture recollected when the name of that organisation is heard or conveyed to the customer's mind (Bravo et al., 2009). In the banking environment, corporate image is a useful tool a bank can use to distinguish itself from the rest as an outcome of communication practices that organisations use to disseminate a particular message that represents strategic intents, reflecting their core values (Bravo et al., 2012).

2.5 Repurchase intention

Repurchase intention denotes a customer's positive conclusion to continue supporting their current service provider and continuously engaging in future transactions with them (Hume & Mort, 2010). In the banking environment, repurchase intention reveals customer desire to upgrade, modify or purchase new banking products on a continuous basis (Herjanto & Amin, 2020). For instance, a customer may want to increase a credit card account limit upgrade from traditional savings to a cheque account, or purchase alternative products such as wealth management or investment products. Accordingly, Tabrani, Amin and Nizam (2018) suggest that repurchase intention is equally a symbol of commitment and a sign that a bank is performing well in satisfying customer needs and requirements.

3. CONCEPTUAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT

The literature revealed that numerous scholars have developed models to examine the influence of CSR on essential concepts such as brand satisfaction and loyalty (Al-Ghamdi & Badawi, 2019), corporate reputation (Bianchi et al., 2019) and purchase intentions (Sharma, Poulouse, Mohanta & Anthony, 2018). However, no study provided a comprehensive view of how perceived CSR and corporate image influence customer repurchase intentions in the South African context. Accordingly, this study utilises a single model as a typical interactive measure to gain insight into, which perceived CSR and relationship quality measures mediated by corporate image leads to banking customers' repurchase intention. The model designs of Carroll (1979), as well as Tian, Wang and Yen (2011), focusing on CSR measures, were adopted. Figure 2 depicts the study's proposed model.

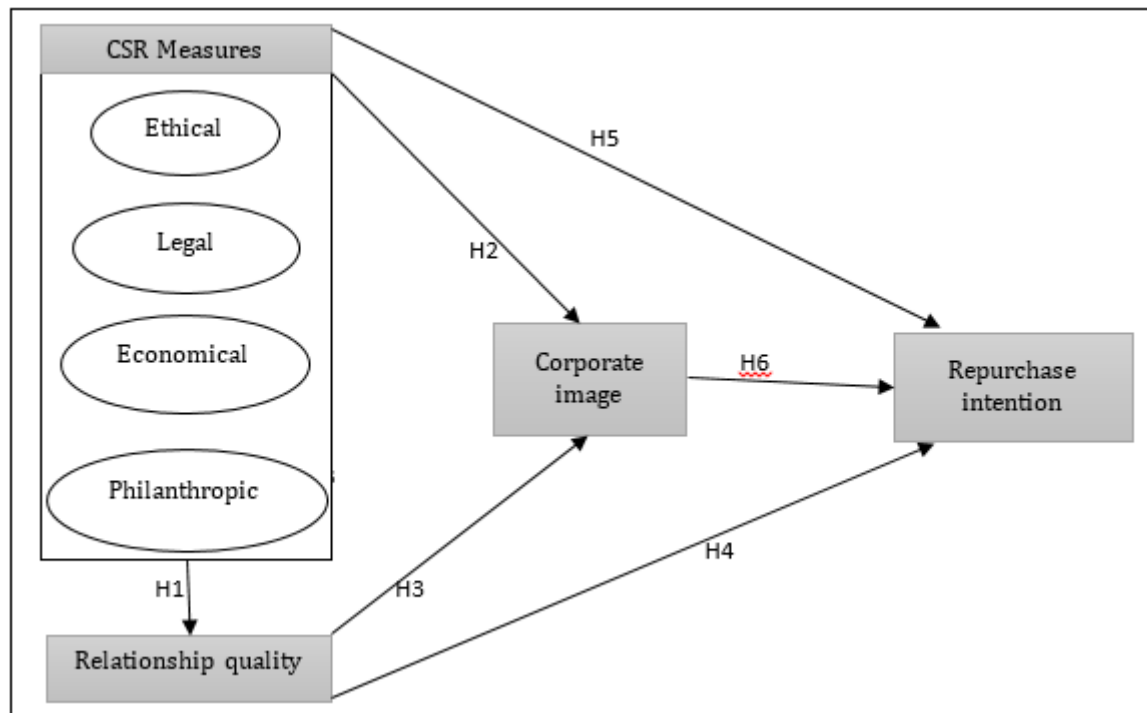

Figure 2: Study model

To test the influence and association between the banks' CSR measures and relationship quality leading to customer repurchase intentions, the following hypotheses were developed:

H1: There is a positive relationship between CSR and relationship quality.

H1a: Relationship quality is positively influenced by the ethical measure of CSR.

H1b: Relationship quality is positively influenced by the legal measure of CSR.

H1c: Relationship quality is positively influenced by the economic measure of CSR.

H1d: Relationship quality is positively influenced by the philanthropic measure of CSR.

3.1 CSR and corporate image

Corporate image has been established as a fundamental precursor to corporate valuations using rational susceptibility between organisations and their stakeholders (Alwi & Kitchen, 2014). It is argued that CSR influences corporate image intellectually and emotionally, even though the valence of its effect may differ from customer valuation procedures (Martínez & Rodríguez-del-Bosque, 2013). Some authors found that CSR does have a significant relationship with corporate image (Stoyanov, 2017; Wu & Wang, 2014). Thus, it is hypothesised that:

H2: There is a positive relationship between CSR and corporate image.

3.2 Relationship quality and corporate image

The influence of organisational relationship quality on its corporate image can be viewed as the basis for shaping and intensifying customer trust and commitment towards the organisation, especially if customer needs and requirements are fully met or satisfied (Wellyan, 2016). Kim and Kim (2016) posit that relationship quality significantly impacts customer decision-making processes when formulating an organisational corporate image to which they can commit to and trust. Thus, this study is underpinned on the basis that one key objective of banking institutions investing in CSR initiatives is to intensify corporate image that improves customer relations.

Wellyan (2016) found that a positive relationship between relationship quality and corporate image exists. Thus, in this study, it is hypothesised that:

H3: There is a positive relationship between relationship quality and corporate image.

3.3 Relationship quality and repurchase intention

Jiang, Shiu, Henneberg and Naude (2016) acknowledge that when customers perceive the quality of their relationship with a supplier to be strong, they tend to buy more and less likely to switch to other service providers. This suggests that a direct positive relationship exists between customer affective commitment as an antecedent of supplier relationship quality and customer repurchase intention (Bianchi et al., 2019). Customers will more likely develop a positive repurchase behaviour once they observe robust relationship quality levels, as presented by their service providers (Kim & Kim, 2016). Accordingly, it is hypothesised in this study that:

H4: There is a positive relationship between relationship quality and repurchase intention.

3.4 CSR and repurchase intention

Repurchase intention refers to customer decisions to re-buy similar products or services from the same supplier when it is beneficial for them to do so on a continuous basis (Vyas & Raitani, 2014). Banking customers also weigh the risks and costs involved with switching to alternatives (Lewis & Soureli, 2006). Uhlig and Mainardes (2019) also found that service providers' CSR initiatives encourage customer repurchase intention. However, this happens on the condition that the customer's previous buying experiences were satisfying. Thus, this study also hypothesises that:

H5: There is a positive relationship between CSR and repurchase intention.

3.5 Corporate image and repurchase intentions

Corporate image signifies how the organisation is perceived when customers see or hear the service provider's name (Bozkurt, 2018). Two components, namely emotional and functional elements that constitute corporate image (Foroudi, Jin, Gupta, Foroudi & Kitchen, 2018), influence customer decision-making processes of making repurchases or not, depending on their satisfaction levels fuelled by past experiences (Mulatsih et al., 2017). Kim, Song, Lee and Lee (2017) also found that a significant relationship between corporate image and repurchase intention does exist. Therefore, it is hypothesised in this study that:

H6: There is a positive relationship between corporate image and repurchase intention.

4. METHODOLOGY

4.1 Research approach

This study applied a deductive research approach to test the research hypotheses and examine the underlying relations among the study constructs. The study used a quantitative, self-completed, structured survey questionnaire to collect data and validate the association between the proposed study constructs as suggested by Burns and Bush (2014). Preceding studies utilised this method in examining the significance of CSR measures on customer perceptions, using constructs such as satisfaction and loyalty (Halim & Hermawan, 2017) and thus, this study also employed this approach.

4.2 Research measures

To operationalise the banks' CSR initiatives, relationship quality, corporate image and repurchase intention constructs, the study utilised question items that pursued assessment of different measures of CSR and the effect of relationship quality on corporate image. The study involved items that epitomise the four measures of CSR proposed by Carroll (1979). The scale items for all study constructs were adapted from previous CSR, corporate image, relationship quality and banking research studies. CSR activities were assessed using scales adapted from Vyas and Raitani (2014) to evaluate the ethical measure with four items and philanthropic measure with five items. The scales were verified by Martínez and Rodriguez-del-Bosque (2013). The scale items used to assess the economic and legal responsibility measure with four items each were adapted from Huang et al. (2014). In addition, the measurement scale for customer repurchase intention using four items was adapted from the same authors. The scales used were modified in terms of the wording to fit this study's context.

4.3 Research instrument

A self-completed structured questionnaire was used for its cost-effectiveness and due to its comparative ease of use to record and analyse data (McDaniel & Gates, 2013). This resulted in a slight adjustment in the wording of certain questions in the instrument. A five-point Likert scale anchored with 'strongly disagree' and 'strongly agree' was employed to rate the study participant's level of agreement with the items. The study questionnaire was reviewed by two marketing research professors and one industry expert to assess content validity and question structure and to acquire feedback on the design and precision of the instrument before the collection of data.

5. DATA COLLECTION

A non-probability convenience sampling method commonly used in consumer behaviour research in the banking environment was employed in this study (Wiid & Diggines, 2015). Data were collected from banking customers in the Vaal Triangle region of Gauteng province in South Africa. The bank intercept approach was applied to gather data from banking customers who had accounts and subscribed to any of the five selected retail banks alluded to earlier. The study respondents were given a consent form to sign in admiration of the research ethical standards and principles, before data were collected (Wiid & Diggines, 2015). A pilot study was first carried out with 40 banking service customers to assess the study instrument's reliability and validity and remove any undesirable items to eliminate errors (Malhotra, 2010). Subsequently, the main survey with 600 questionnaires was undertaken. Only 551 usable questionnaires were collected and deemed fit for analysis after discounting the incomplete and faulty forms. This represents a response rate of 92 percent.

6. DATA ANALYSIS

The Statistical Package for the Social Sciences (SPSS) 26.0 version and Analysis of Moment Structures (AMOS) 26.0 version were used to analyse the reliability and validity of data. Given its ability instantaneously test a series of dependent relationships, AMOS was used as it fosters the overall method of data analysis renowned as structural equation modelling (SEM) to test model causality (Arbuckle, 2013). The process of data analysis began with data cleaning for editing and coding purposes (Malhotra, 2010). Cronbach's alpha values (α) and composite reliability (CR)

were calculated to validate the consistency of the questions. Confirmatory factor analysis (CFA) was carried out (Kinnear & Gray, 2010) to validate construct fundamentals that formed sets of answers (Costello & Osborne, 2005). To assess the accuracy and determine the rigor of the study constructs in relation to what exists, the validity analysis recommended by Wiid and Diggines (2015) was performed. This was achieved through the use of CFA to establish whether the items could be put together and validated by incomprehensible constructs (Bagozzi, 1994). The convergent validity was verified using factor loadings of all items that had to be greater than 0.5, including confirmation of discriminant validity using the confidence interval greater than 0.5 and the average variance extracted (AVE) for each factor. In both cases, the minimum requirements for reliability, convergent and discriminant validities were met.

Prior to testing the hypothesised associations in the purported study model, the reliability of the focal constructs was assessed in conjunction with convergent and discriminant validities through CFA measurement model. The measurement model generated statistical values that corresponded with the recommended thresholds for a good model fit (Bagozzi & Yi, 2011). With the use of all items excluding those omitted following the pilot survey, satisfactory fit data (CMIN/DF 3.07; GFI 0.911; NFI 0.942; RFI 0.950; IFI 0.905; TLI 0.908; CFI 0.963), with a RMSEA value of 0.06 and SRMR at 0.038 were recorded and confirmed the absence of unidimensionality of the measures (Anderson & Gerbing, 1988). Although the chi-squared test was not significant in the confirmed study model, it was admitted being insistent and inapt to the sample size (Fornell & Larcker, 1981), thus, indicating the model fit. In contrast, Bagozzi and Yi (1988) assert that other fit indices such as CFI, RFI and RMSEA are better suited to measure the model fit. The CFI for the study sample was greater than 0.95, signifying that the measurement model represented a satisfactory fit to the applicable data. The validation of the measurement model was performed to evaluate the structural model. Arslan, Yilmaz and Aksoy (2012) state that the structural model summarises the relationships between latent variables by providing estimates of construct correlations. Following valuations of the measurement model's worth, the structural model was evaluated using AMOS version 26.0, to test statistical competence exercising the maximum likelihood estimates (MLE) (Bagozzi & Yi, 2011).

7. RESULTS AND DISCUSSIONS

7.1 Reliability and correlation analysis

The internal consistency of all measurement values surpassed the 0.70 boundary endorsed by Pallant (2020), henceforth offering satisfactory Cronbach alpha value (α) results. The Pearson correlation analysis was applied to examine the correlation between variables. The effect of associations was established at 0.5 to 1.0 (strong relationship), 0.3 to 0.5 (moderate relationship), 0.1 to 0.3 (weak relationship) and 0.0 to 0.1 (very weak or no relationship) at a significance level of 0.01, consistent with Choudhury's (2009) suggestion. The study results reveal that all constructs positively interrelate with each other as correlations are purged lower than 1, signifying the non-appearance of multicollinearity in the data set (Wiid & Diggines, 2015). The reliability and correlation coefficient matrix results are presented in Table 1.

Table 1: Descriptive statistics and correlation matrix between variables

| Variables | (α) value | Mean | SD | ETH | ECO | PHI | TRU | SAT | COM | CORP | REP |
|------------|--------------------|------|------|---------|---------|---------|---------|---------|---------|---------|-----|
| ETH | 0.77 | 4.40 | 0.54 | 1 | | | | | | | |
| ECO | 0.77 | 4.40 | 0.54 | 0.371** | 1 | | | | | | |
| PHI | 0.81 | 4.38 | 0.57 | 0.315** | 0.308** | 1 | | | | | |
| TRU | 0.90 | 4.33 | 0.72 | 0.422** | 0.292** | 0.444** | 1 | | | | |
| SAT | 0.90 | 4.44 | 0.72 | 0.342** | 0.290** | 0.364** | 0.692** | 1 | | | |
| COM | 0.88 | 4.25 | 0.66 | 0.186** | 0.237** | 0.273** | 0.426** | 0.435** | 1 | | |
| COR | 0.84 | 4.30 | 0.62 | 0.075 | 0.078 | 0.102* | 0.251** | 0.245** | 0.233** | 1 | |
| REP | 0.89 | 4.37 | 0.66 | 0.137** | 0.047 | 0.197** | 0.342** | 0.306** | 0.302** | 0.269** | 1 |

** Correlation is significant at the 0.01 level (2-tailed), ETH=Ethical; ECO=Economic and legal responsibility; PHI=Philanthropic; TRU=Trust; SAT=Satisfaction; COM=Communication; COR=Corporate image REP=Repurchasing intentions.

The following satisfactory data fit indices were recorded: CMIN/DF 2.441; GFI 0.884; NFI 0.879; RFI 0.863; IFI 0.925; TLI 0.914; CFI 0.925, with the RMSEA value of 0.061. Taking from the outcomes of the measurement and the structural model’s valuations, the next step was to examine and validate the proposed hypothesised construct associations. The path coefficients that emanated from SEM simplified all the suggested hypotheses and both statistically insignificant and significant associations of the hypotheses at a level of $p < 0.05$ and $p < 0.01$. The p value specifies a level of confidence that accordingly advocates that the hypothesis is significant and supported as proposed by Zikmund, Babin, Carr and Griffin (2013). Table 2 demonstrates the study’s hypotheses testing results.

Table 2: The hypotheses testing results

| Hypothesis statement of path analysis | Estimate | P-value | Result |
|---|----------|---------|------------------|
| There is a positive relationship between CSR and relationship quality. | 1.273 | 0.001 | H1 Supported |
| There is a positive relationship between CSR and corporate image. | -0.211 | 0.069 | H2 Not supported |
| There is a positive relationship between relationship quality and corporate image. | 0.312 | 0.001 | H3 Supported |
| There is a positive relationship between relationship quality and repurchase intention. | 0.714 | 0.001 | H4 Supported |
| There is a positive relationship between CSR and repurchase intention. | -0.690 | 0.001 | H5 Supported |
| There is a positive relationship between corporate image and repurchase intention. | 0.343 | 0.001 | H6 Supported |

According to the supported hypotheses, the banking customer’s fulfilment following their service provider’s relationship quality and the corporate image does significantly influence the envisaged customer repurchase intention outcome. The path coefficients that originated from SEM clarified all recommended hypotheses and both statistically significant and insignificant relationships of all the hypotheses at a level of $p < 0.01$ and $p < 0.05$. Five pathways from the proposed study model were supported. The p values point out a level of confidence, which, therefore, means that the hypothesis is supported and significant. CSR had a positive and significant influence on relationship quality at $p < 0.01$ and therefore H1 was accepted. H3 was also supported, indicating that relationship quality had a significant and positive influence on corporate image. This finding also corresponds with Wellyan’s (2016) finding in his study in Indonesia that there is a significant positive relationship between the two constructs in the passenger transport industry. H4 that purported relationship quality to be significant and positively impacted repurchase intention was

supported. This finding is consistent with Kim and Kim's (2016) finding in their study in the USA that a significant relationship does exist between the two constructs in the hotel industry. H5 was likewise supported as CSR had a positive and significant influence on repurchase intention. H6 hypothesised that corporate image has a positive and significant impact on repurchase intention, this hypothesis was also supported. However, H2 proposed that CSR has a positive influence on corporate image, unfortunately, it was not supported with a p-value of 0.069, which was greater than the $p < 0.05$ threshold.

8. MANAGERIAL IMPLICATIONS

This study offers valuable insights for marketing practitioners and academics regarding banking service providers' CSR initiatives and their influence on customer behavioural patterns. According to the researcher's knowledge, this study is the first to establish an empirical association between CSR measures and relationship quality leading to repurchase intentions moderated by corporate image in the South African banking context. Relationship quality appeared to be having a positive impact on corporate image and significantly influence customer repurchase intentions, corroborating Alhouti, Johnson and Holloway's (2016) findings that a positive relationship between CSR and repurchase intention does exist. When banking service providers engage in CSR initiatives, customers tend to be keen to repurchase their services. In addition, it is argued in this study that corporate image does not quite capture the impact of CSR on repurchase intention, owing to three possible reasons. First, customers may be doubtful of the exact intentions of the bank to embrace CSR. Secondly, CSR measures are perhaps viewed as part of the banks' role in enhancing corporate image and in turn, customers do not value this greatly in making decisions to repurchase banking services. Thirdly, customers could be paying more attention to economic and legal responsibilities and be less concerned with ethical and philanthropic tasks due to a possible lack of understanding of the banks' practice of CSR activities.

9. CONCLUSION

The objective of this study was achieved as the results showed sufficient statistical evidence suggesting the existence of differences in customer perceptions about CSR, relationship quality, corporate image and repurchase intention, as H1, H3, H4, H5 and H6 were supported. Remarkably, the study established that CSR wielded a negative and insignificant influence on corporate image and, hence, H2 was rejected. This implies that banks' CSR initiatives are less important in augmenting corporate image and promoting customer repurchase intentions in the South African banking environment. Moreover, the study offered practical strategies on how banking service providers should understand the interrelationship between the proposed study constructs. The use of suggested strategies geared towards understanding customer purchase behaviour and how to improve repurchase intentions could craft a competitive edge by integrating CSR initiatives that inspire relationship quality and corporate image in the banking environment of an emerging market. Therefore, the study concludes that first, the role of CSR as a source of competitive advantage should be established to improve the quality of relationships. Secondly, it is imperative to build marketing strategies that incorporate CSR initiatives that are customer-focused by commissioning the three validated constructs in the study model (relationship quality, corporate image, and repurchase intention).

ASSESSING THE FACTORS INFLUENCING PROCUREMENT SUCCESS IN HIGHER EDUCATION INSTITUTION. THE CASE OF ONE UNIVERSITY OF TECHNOLOGY

K. Masuku

Vaal University of Technology, Vanderbijlpark, South Africa

O.T. Matsheke

Vaal University of Technology, Vanderbijlpark, South Africa

ABSTRACT

Procurement is a method used to find and source goods and services. This method involves the sourcing and purchasing and covers all activities from identifying of potential suppliers through to the delivery from the supplier to the user. The public procurement process needs to be understood by all parties involved. This study examined the factors influencing procurement success in one university of technology based in Gauteng, South Africa. The qualitative approach was adopted in this paper. In-depth interviews were conducted with the 12 participants who were selected through convenient sampling. The participants that are included in the sample size are the supply chain senior manager, one senior buyer, four assistant buyers and six interns. The research employed a thematic approach to analyse and interpret data. The findings of this paper revealed that just-in-time (JIT), procurement performance and information sharing are able to influence the procurement success in a higher education institution. The research aim was to investigate factors influencing procurement success in higher education institutions. Recruitment of non-qualified procurement staff, who are not competent enough to manage and conduct the procurement process, has led to the neglect of procurement activities. There must be a complement of employees within procurement that are young and old so that there is a balance of knowledge and experience. This will ensure that there is continuity and a strong legacy left behind when the old employees retire. Higher education institutions should adopt JIT principles in all their procurement processes so that unnecessary handling costs are avoided. The use of e-procurement systems is recommended.

Keywords: Just-in-time, performance of procurement, information sharing.

1. INTRODUCTION

Since the birth of South Africa's (SA) democracy, procurement has been used as a strategic instrument to allow the South African government to put transformation policies in place to improve the socio-economic status of the country (Turley & Perera, 2014). Traditional methods of procurement have come under pressure to change and they need to be replaced with the conventional approaches that will accommodate modern ways of business (Adagala, 2014). Abundant research has been conducted on procurement, but it is not clearly explained as to what specific factors influence procurement success in Higher Education Institution (HEIs), particularly universities of technology (UOTs). Procurement is a method to find and source goods and services; this method involves the sourcing and purchasing, while covering all activities from identifying of potential suppliers through to the delivery from the supplier to the user (Bekele, 2015). It is important that the acquired goods and services are sourced from the right source, are of the correct

quality, in the right quantity, at the right price and at the right time in order to maintain and manage the company's primary and supporting activities (Bekele, 2015).

2. LITERATURE REVIEW

This section provides the literature review on just-in-time (JIT) strategy within HEIs, performance of procurement and information sharing.

2.1 Adoption of just-in-time (JIT) by higher education institutions

The JIT concept has been welcomed by businesses as a method to improve performance and reduces cost within their processes to gain competitive advantage in a very competitive business environment (Taghipour, Hoang, & Cao, 2020). JIT is a tool introduced by Toyota Motor Corporation in Japan to eliminate any waste within the production line of cars to meet the customers' needs Shah and Patel (2018). The JIT philosophy advocates that no activity in the production line will take place without a need from the customers (Rahmani & Nayebi, 2014). The JIT technique can be used by any business, whether public or private. The aim of this concept is to improve the movement of goods and services just when they are needed. The concept of JIT can be used by HEIs in managing their resources and ensuring that they are operating optimally. Prudent inventory systems involve the economic order quantity (EOQ) model, fixed order system model and fixed order period system model (Muchaendepi, Mbohwa, Hamandishe & Kanyepe, 2019., Ondyeki, 2019). The economic order system is a model that is used by organisations to determine the number of items to order in order to reduce the handling cost and the cost associated with order processing (Meileni, Putra, Apriyanti, Satriadi & Oktapriandi, 2020). According to Sulaeman, Waluyo and Ali (2019), public higher education institutions are funded by state budgets; hence, they need to be accountable for their expenditure.

2.2 Performance of procurement

The aim of procurement is to source goods and service from reliable service providers to provide goods and services that are of high quality and be delivered on time and at an economical price (Duke Agyeman Fredua, Okyere & Adams, 2020). Procurement is one of the most important functions of any organisation and it plays a strategic role in ensuring that the organisation achieves its set goals. Kakwezi and Nyeko (2019) argue that "until an organisation measure purchasing performance, they will never know how well they are performing". For the procurement department to achieve its functions, performance must be measured to verify if it meets its objectives. Monitoring of procurement performance enables managers to evaluate how the procurement is performing and identify areas of improvement in order to improve the overall procurement performance (Saad, Kunhu & Mohamed, 2016).

Procurement performance relates to the reduction of operational cost while ensuring that the organisation remains profitable (Schütz, Kässer, Blome & Foerstl, 2020). Procurement's main area of concern is the effectiveness and reliability of a procurement system. Price variance, contract utilisation, supplier performance, procurement cycle time and variability, payment processing time, procurement cost and employee training are among the indicators on how well a procurement is performing (Saad *et al.*, 2016). When the university is engaging in supplier selection it needs to ensure that suppliers selected will be able to meet the mandate of the university in supplying goods

and services that are of high quality. Cost reduction, delivery on time and system flexibility are some of the key indicators of procurement performance (Okoth, 2019).

2.3 Information sharing

Information is one of the important aspects that an organisation can use to improve and achieve its goals. According to Lotfi *et al.* (2013) information sharing means distributing useful information for systems, people or organisational units

Several studies have shown that the sharing of information can yield positive results for the organisation's supply chain (Sheikhi, Goodarzi, Nowrozonejad, & Sheikhi, 2018., George & Pillai 2019). The sharing of information helps the organisation to coordinate its resources and all the supply chain activities (Wu, Yenyurt, Kim, & Cavusgil, 2006). Different organs of the organisation can collaborate and work together using information sharing to cut inventory cost and to improve the efficiency of the supply chain (Lotfi Mukhtar, Sahran & Zadeh 2013). Collaboration refers to two or more organisations joining forces to work together, sharing information and the buying power in pursuit of achieving a common goal (Meehan, Ludbrook, & Mason, 2016). Collaboration plays a strategic role in higher education institutions; it allows institutions to share knowledge, resources and sourcing power, and increases buyer side leverage (Meehan *et al.*, 2016). Collaboration can be used to form partnerships with suppliers in order to share resources and solve problems. The partnerships that are entered into during collaboration will assist the higher education institutions to share key resources such as technology and markets.

3. RESEARCH METHODOLOGY

This paper adopted the qualitative approach. The qualitative research approach is suitable for this research because it gives the researcher first-hand information from the participants pertaining to their personal experiences, which is difficult to collect when using a quantitative research approach (Abutabenjeh & Jaradat, 2018). Aspers and Corte (2019) state that the qualitative research approach uses existing studies to collect information from people's personal experience and utilises open-ended questions, comprehensive interviews and field notes. The use of the qualitative approach allows the researcher to use non-statistical methods to draw an understanding on the data collected. This means that the qualitative approach does not use a statistical method but it employs a number of realities, such as lived experiences, behaviours, social trends and different cultural dynamics that are found in the social settings and personal lives (Rahman, 2017). The employment of the qualitative approach gives the researcher a chance to draw deep insights into the problems presented to them (Tsushima, 2015). The qualitative approach gives the researcher the flexibility to interpret the data collected in different ways that they see fit for the particular scenario presented to them. In this way, the participants are given the freedom to express themselves and influence the direction of the research.

The target population for this study was the 17 employees that work in the procurement department in a higher education institution. Convenient sampling, a non-probability sampling method was deployed to select 12 participants from various levels of the organisation who could provide enriching responses and openly share their diverse experiences. Convenient sampling is a method of sampling that uses those that are conveniently available (Kapur, 2018). Pascoe (2014) explains that convenience sampling entails studying and extracting data from respondents within the target

population that are nearest to and readily accessible to the researcher. The participants included in the sample size were the supply chain senior manager, one senior buyer, four assistant buyers and six interns. Face-to-face, in-depth interviews were conducted to collect data. Kapur (2018) explains that open-ended questions are used to give a chance to the respondents to give their responses freely. The interview sessions were booked in advance with each participant. Each interview took between 20 and 30 minutes. The researcher ensured that saturation was reached during data collection by probing for more answers, but answers remained the same.

Thematic analysis was utilised to manually analyse data and derive meaning from the raw data collected. Thematic approach is a method used to put data into themes that bring meaning to the data collected. It organises information into patterns that make sense on the data set (Terry, Hayfield, Clarke & Braun, 2017) The themes that are found in the data set are focused on the lived experiences of the participants (Sundler, Lindberg, Nilsson & Palmér, 2019). Thematic familiarity is gained through understanding texts and becoming familiar with data and looking for special characters on the data findings. Search for meaning and theme is achieved through looking for meaning on lived experiences presented by participants and constructing patterns from the lived experiences. From the patterns constructed, the researcher begins to see themes coming together (Sundler *et al.*, 2019). After the researcher has constructed and understood the themes presented by data, the themes are organised and jotted down to bring meaning. The theme outcomes should be able to describe the actual meaning of the lived experiences.

The concept of trustworthiness was strictly observed to evaluate the quality of the study. A qualitative research's trustworthiness is measured by its dependability, transferability, credibility and confirmability (Korstjens & Moser, 2018).

In terms of dependability, the researcher ensured that the data collection methods were described in full detail and common understanding between the researcher and the participants was ensured. Moreover, participants' responses were recorded accurately to avoid misinterpretation and misrepresentation of data. Dependability is the consistency and reliability that is presented by research findings, which can be used by other researchers to support their work (Moon, Brewer, Januchowski-Hartley, Adams & Blackman, 2016). The transferability can be measured by how well the findings will be able to be transferred to other social settings by different researchers (Korstjens & Moser, 2018). In order to ensure transferability, convenient sampling was used to increase the trustworthiness of the data and the researcher further provided enough information and clarity about the context of the study. Moreover, credibility was enhanced through avoiding potential researcher bias and shifting the interpretation of what the participants said to fit a certain narrative. Credibility is the confidence that can be placed on the research findings and how truthful the research findings are (Nowell, Norris, White & Moules 2017). The credibility of the research is measured by the truthfulness the information gathered. Confirmability is found when the data accurately depicts the actual information provided by the participants (McInnes, Peters, Bonney & Halcomb, 2017). Confirmability was ensured by being neutral and not taking sides. The aim was to bring a fresh and new perspective to the body of knowledge.

4. ETHICAL CONSIDERATION

The researcher has the responsibility of protecting the dignity of participants, consider participants' safety and the wellbeing of the participants. The key ethical aspects of research were

adhered to. For instance, the researcher ensured that the study was approved through obtaining a permission letter. Participants were given full details of the study and were informed of their right to voluntarily participate as well as the right to withdraw from the study. The researcher further ensured that participants were not exposed to any harm or risk during their participation in the study. Moreover, all data collected were kept confidential and participants remained unanimous throughout the course of the study and the reporting process. The privacy of the participants involved in study was protected. This means that information provided during the study was strictly limited to the researcher and the supervisor of the study. A consent informed letter was developed that explained to participants what this research is all about and that they were free not to participate if they felt uncomfortable about the content contained in the research.

5. RESULTS AND DISCUSSION

This section provides the findings and the interpretation of the results. The findings are codified and themed. The findings relate to the research questions that this research set out to answer.

5.1. Themes

Certain themes emerged from the data and these themes are discussed below. The opened-ended questions were asked to allow respondents to share freely their opinion and lived experience (P denotes participant).

5.1 Adoption of just-in-time (JIT) by higher education institutions

Theme 1: Understanding of JIT

From the outcome of the question it showed that most of the participants understood and are familiar with the concept of JIT. The answers given by respondents are similar and show that the staff members know how JIT works.

P1: *“It helps to reduce cost with minimum inventory on hand”*. This is in line with Okoth’s (2019) argument that cost reduction, delivery on time and system flexibility are some of the key indicators of procurement performance. One participant did not know how the JIT concept is applied when sourcing goods and services. This shows that maybe the participant is not aware of how this concept works or was just confused with the terminology.

Sub-theme 1.1: Application of JIT when procuring goods and services

The responses gathered from participants showed that the JIT principle is used when sourcing for goods and services. P9 said *“goods and services are sourced when there are needed in order to minimise the holding stock and costs associated with holding stock”*. Muchaendepi et al. (2019) agree with this view and indicate that the (EOQ) model is used to determine the optimal order size for each inventory items, it reduces the ordering and carrying costs. Mankazana and Mukwakungu (2018) stress that to implement the JIT effectively, organisations need to have a sound relationship with their suppliers.

Sub-theme 1.2 Procurement systems

The information gathered from the participants shows that the procurement system is used to facilitate the procurement of goods and services in this institution. The respondents alluded that they use the oracle system.

P2: “This system registers suppliers and also perform due diligence in the supplier to check the risk. then the system invites the suppliers and all information related to the tender is being shared in the system to ensure compliance and transparency”.

The system is intelligent enough to do all the background checks on the suppliers and invite all the qualifying suppliers to bid. This is similar to the economic order system model that is used by organisations to determine the number of items to order in order to reduce the handling cost and the cost associated with order processing (Meileni *et al.*, 2020).

The responses show that the system has less human interruption and it is transparent when it comes to supplier selection. The awarding of the tender is given to best suppliers that meet all the specifications.

The respondents also mentioned that they make use of the requisition form to get needed goods from each department within the institution. *P7: “The requisition forms are completed on the system and shared with all the relevant people on the system”. “There is an online portal that is used to fill the requisition forms”. P10: “The use of technology minimises risk of corruption, speeds up time and ensures proper compliance with the process is done. The use of technology it enhances the speed, performance and turnaround time for procurement which gives it the ability to respond to customers’ needs on time. “*

This indicates that the procurement department is moving with the times in that it makes use of technology to complete requisition forms to avoid any errors and a time-consuming manual process.

Sub-theme 1.3 The turnaround time of receiving items procured from the supply

A participant’s response indicates that it all depends on the type of commodity that is being procured. *P5: “The lead time, for non-critical items it can take 1-2 weeks to be delivered. However, for critical and overseas foreign equipment it takes up to 12 weeks”.* It clearly shows that the minimum turnaround lead time is one week.

5.2 Measurement of performance procurement

Theme 2: Performance of procurement

The participants indicated that lengthy procurement processes impact procurement performance by reducing the targets that are set by procurement and that will affect the performance and profit of the institution.

P7: “Lengthy procurement processes impact the institution negatively in a way that the institution will not be efficient, customers will not be satisfied and lead to ineffective performance within departments in the institution”.

This indicates that lengthy procurement processes cause delays of procurement of goods and services and this will lead to other procurement goals not being met in the institution. This view coincides with Saad *et al.* (2016) that monitoring of procurement performance enable managers to evaluate how the procurement is performing. Anane and Kwarteng (2019) deliberate that performance procurement lays the basis of effective control of resources and validates the value of procurement functions within the organisation.

Sub-theme 2.1: Competency (skills and experience) impact procurement performance”.

The outcome from the question clearly indicates that lack of skills and experience does impact on performance of procurement as this will lead to not following proper procurement governance processes and procedures, which will lead to unnecessary expenditure. The majority of participants indicated that *“lack of skills and experience does impact the institution performance negatively and also efficiency of the institution does get affected”*. Okoth (2019) posits that the recruitment of non-qualified procurement staff who are not competent enough to manage and conduct procurement process has led to the neglect of procurement activities. However, P12 states *“skill and experience does not real affect procurement performance as people get skilled and experience as they continue to do their job”*. It clearly indicates that sometimes experience does not matter as long as you have experienced people around you who will train you to do the job. Most of the participants indicated that they have not yet experienced any problems with poor performance procurement. This clearly indicates that the institution’s procurement processes are performing well in ensuring that there is no poor performance.

Sub-theme 2.2 Planning culture among users of university and its impact on procurement performance

All the participants indicate that the implementation of planning culture is crucial as poor planning will lead to goods being delivered late and also put unnecessary pressure on procurement officers to perform the procurement process. P2: *“Planning culture increases efficiencies, promote customer satisfaction and reduces cost”*. The responses indicate that a culture of planning does drive the procurement performance as this will make sure that things are planned in advance to avoid unnecessary delays in deliveries and sourcing of goods and services. Anane and Kwarteng (2019) point out that there is a concern that procurement performance is rarely measured in the public sector. The inability to establish performance standards affects performance functions and leads to irregular anticipations, which affect decision making.

Sub-theme 2.3 Resource allocation (budget allocation) influence procurement performance

According to Sulaeman *et al.* (2019) public higher education institutions are funded by state budget hence they need to be accountable in their expenditure.

All the participants agree that budget allocation does influence procurement performance. The responses indicate that getting budget allocation on time is important as this will help the institution to do planning on time. Also, without an approved budget there will be no procurement process and suppliers will not be paid. P5 said *“The budget amount guides the purchasing officers on which processes to follow to obtain approvals”*. Procurement performance relates to the reduction of operational cost while ensuring that the organisation remains profitable (Saad *et al.*, 2016).

Sub-theme 2.4: Traceability or feedback influence performance of procurement?”

It was noted from participants’ responses that feedback is important as this will create accountability and responsibility from procurement officials. P11: *“Feedback helps the procurement to improve its processes and see where there are lacking. Customers and end users able to give feedback to procurement that will assist procurement to work on its processes”*

5.3 Information sharing

Theme 3: The importance of information sharing

George and Pillai (2019) posit that information is essential for everyday operations at each level of the supply chain due to its ability to connect various supply chain stakeholders and allows them to coordinate activities. Responses from participants indicate that collaborations with suppliers are important as this will massively, create employment for small companies which is good for the economy of our country. Through working with suppliers, the institute contributes positively to the growth of small businesses and enable them to be better enterprises that will be able to compete with bigger businesses.

P9: “Continuous sharing of information and making it available to key stakeholders in the supply chain allows quicker and more reliable business decisions that provide competitive advantage.”

Sub-theme 3.1: Training about information sharing

P1: “I believe that we should emphasise on more training with regards to information sharing. Employees and partners should know the importance and the power of information in the supply chain”.

This notion is supported by Anderson, Müller, and Pelletier (2015) that public procurement process needs to be understood by all parties involved such as suppliers, sourcing entities, businesses, government, professionals, and the public in general. As much as these guidelines have been put in place, most public entities do not adhere to these policies and procedures, which has led to the sourcing of wrong products. The responses can also be linked with Mathu (2019) who states that long cooperation and coordination of information exchange in the supply chain leads to an improvement in the competitiveness of the companies involved.

The responses from participants indicate that all procurement officials sign a non-disclosure agreement with the chief financial officer. P8: *“All the information shared through the institution one cloud drive so that there is transparency and information is stored in one place”.* This indicates that there is a process that is followed to ensure that institution information shared is not easily shared with outsiders. P6: *“other methods that are used by the institution to share information are meetings and engagement with different stakeholders”.* George and Pillai (2019) stress that information sharing is a key initiative for managing the supply chain in order to achieve higher performance gains, additionally offers many benefits such as reduced bullwhip effect, better coordination among various activities, taking better decisions and reduced uncertainties in supply chain and better understanding of customer needs and faster response to market changes. This view is also supported by Chopra Meindl and Kalra (2013) that supply chain coordination requires each stage of the supply chain to share information and consider the impact of its actions. P3: *“Sharing*

of information has helped the institution in a way that we all speak the same language, there is no repetition of work and it avoids duplication. The processes and procedures are well known to the entire organization when information is shared accordingly". It was also noted that sharing of information helps the institution with the dissemination of strategic goals and objectives at tactical and operational level to seamlessly execute and implement the tasks at hand.

Sub-theme 3.2: Collaboration with suppliers

Effective supplier management is directly linked to a higher level of performance and compliance. Strategic collaboration will certainly improve performance of supply chains (Mani, Gunasekaran & Delgado, 2018). P4: *"Through working with suppliers, the institution contributes positively to the growth of small businesses to be better enterprise that will be able to complete with bigger businesses. It increased understanding and improved service."* Mani et al. (2018) further alluded that companies have always been inclined to work with different types of suppliers in different ways. This increases the institution of Broad-Based Black Economic Empowerment (B-BBEE) regulatory status which increased savings and SMMEs delivery capability and create opportunities that will translate to job creation and improved inequalities. The above are some of the benefits of collaborating with suppliers that the institution will achieve.

This clearly shows that there is still room for improvement when it comes to procurement processes to ensure that users can receive what they requested. User training is one of the methods that can be used to train users on how to order goods and services.

6. LIMITATION OF THE STUDY

The study was only limited to looking at factors influencing procurement success in one particular institution and did not compare with other institutions. The views, experiences and perceptions shared in this paper may not necessarily reflect the general views of employees within the institution, as such diversity management issues may be context-specific. It must be acknowledged that the results of this study reflect the views of the organisation under study, therefore, should not be presumed to be universally applicable to all higher education institutions. The time limitation and COVID-19 regulations and protocols made it difficult to reach out for more participants to take part on the research.

7. AREAS OF FUTURE RESEARCH

The focus of the research was to assess the factors influencing procurement success in higher education institutions. The study only looked at one higher education institution and future research can look at other institutions and do a comparison on factors that influence their procurement successes.

8. MANAGERIAL IMPLICATIONS

The focus of this study was to investigate the factors influencing procurement success in higher education institution. The findings of this study will assist procurement managers in implementing JIT in their procurement processes and ensure that the information is shared with all stakeholders to promote high procurement performance.

9. CONCLUSION

The research aimed to investigate factors influencing procurement success in a higher education institution. The researcher used the existing literature to understand factors that influence the success of procurement so that the research question could be answered. The finding of the study indicates that there are many factors that influence procurement success and that contribute positively to the procurement success. These factors include Just-in-time, performance of procurement and information sharing. The flow of information should be seamless between the institution and their supply chain partners. The information that should be shared should be discussed beforehand with their partners and constantly be reviewed throughout the lifecycle of the relationships so that any changes to the conditions are communicated in time. Continuous supply chain training is important so that the management and the workforce stay informed, and they keep their skills up to standard at all times to ensure efficient and effective supply chain operations. The institution should constantly scan their technological environment for new trends and solutions to keep accurate information.

SCULPTING SOCIAL INTERACTIONS AS AN ANTECEDENT OF ENTREPRENEURIAL INTENTION AMONG VAAL UNIVERSITY OF TECHNOLOGY STUDENTS

G. Mothibi

Vaal University of Technology, Vanderbijlpark, South Africa

W. Munyanyi

University of Johannesburg, Johannesburg, South Africa

ABSTRACT

Entrepreneurial intention has been described as the subjective thinking and mental state of an entrepreneur prior to the implementation of entrepreneurial behaviour. Grounded on the social exchange theory, this study sought to examine the influence of social interactions on entrepreneurial intention among university students. Social interaction has been a popular notion with the turn of the new millennium, and it will be interesting to discover how it influences entrepreneurial intention. Despite the significance of social interactions in behavioural and business contexts, it has remained largely under-researched in relation to entrepreneurial intention. This study adopted a cross-sectional descriptive survey design, with data collected through an online questionnaire developed in Google Forms. Confirmatory factor analysis was conducted, followed by structural equation modelling to test the hypotheses made in this study. The results from this study indicate that all the dimensions of information exchange, informal competition and social cooperation have significant positive effects on students' entrepreneurship intention. By examining social interactions in the context of novel dimensions like information exchange, informal competition and social cooperation, this study makes a remarkable contribution to theory and practice.

Keywords: Social interaction; entrepreneurial intention; information exchange; informal competition; social cooperation

1. INTRODUCTION

In both developed and developing economies, entrepreneurship has been regarded as a significant indicator of economic growth (Stamboulis & Barlas, 2014; Bosma *et al.*, 2018). As such, both policymakers and academics have continually sought means to enhance entrepreneurial activity among youth so that the country may yield noticeable financial, cultural and social benefits (Ho *et al.*, 2018). The drive to grow entrepreneurial activity has been encouraged globally because it has been identified as creating employment, high levels of competitiveness and innovation (Barba-Sánchez *et al.*, 2022). More recent scholarly research has also confirmed that organisations and economies that invest in entrepreneurial development among its human capital catalyse economic growth and development (Amoroso & Link, 2018; Stuetzer *et al.*, 2018; Karlidag-Dennis *et al.*, 2020; Zaring *et al.*, 2019). The central argument that these scholars bring forth is that in order to enhance the surgency and growth in new ventures, it is imperative that efforts to measure the level of preparedness among young graduates to start new ventures, at the same time preparing them for entrepreneurial activities (Bacigalupo *et al.*, 2016). According to Ndou *et al.* (2018), nurturing

entrepreneurial intention among university students does not only create a link towards economic development but also a link towards social development and innovation opportunities. With the arguments above in mind, there have been concerted efforts among scholars to measure the level of entrepreneurial intention, especially in developing economies. Entrepreneurial intention has been described as the subjective thinking and mental state of an entrepreneur prior to the implementation of entrepreneurial behaviour. Over the years, research on the entrepreneurial intention notion has increased exponentially, with the factors influencing entrepreneurial intention dominating (Nabi et al., 2018; Martínez-García et al., 2019; Acs et al., 2018). In South Africa, there has been remarkable interest in evaluating the factors that influence entrepreneurial intention among university students (Urban & Chantson, 2019; Letsoalo & Rankhumise, 2020; Nsahlai *et al.*, 2020).

For South Africa, the entrepreneurship drive is more urgent than it may appear, given that unemployment still remains a challenge in post-apartheid South Africa. According to the Quarterly Labour Force Survey (QLFS) released for the second quarter of 2019, the official unemployment rate increased by 1.4 points to 29.0% when compared to the first quarter of 2019 (Statistics South Africa, 2019). This implies that despite the increase in attention to entrepreneurial intentions among students, the economy is still battling with incapacity to create employment. In response to this challenge, this study sought to take up entrepreneurial intention from the viewpoint of a largely ignored potential antecedent of entrepreneurial intentions, social interactions. The majority of the studies have focused on environmental factors, such as entrepreneurial education and structural support, personality traits such as self-efficacy (Maheshwari, 2021), perceived fit (Hsu, *et al.*, 2019) and preferences and beliefs (Boldureanu et al., 2013;). The impacts of social interactions have been observed among individuals in relation to smoking and other habitual behaviours (Cutler & Glaeser, 2010; Fletcher & Marksteiner, 2017) and it is for this reason that this study proposed a relationship between social interactions and entrepreneurial intention. The underlying argument in this study is that by evaluating the dimensions of social interactions among students under the subconstructs, information exchange, informal competition and social cooperation, a relationship can be observed between these constructs and entrepreneurial intention. Therefore, this study aims to provide empirical support for the influence of the social interactions' variable, as measured in terms of the aforementioned subconstructs, on the entrepreneurial intentions of university students. The relevance of this study lies in its capacity to provide a basis for more social activities in the university's extra-curricular activities to promote entrepreneurial spirit among university students.

2. LITERATURE REVIEW

2.1 Theoretical framework

While most of the studies in entrepreneurial intention have been grounded on the theory of planned behaviour (Ajzen, 1991), these studies break away completely from the norm to build the conceptual model upon the social exchange theory. Because many studies were based on the theory of planned behaviour, the same arguments that entrepreneurial intention is a result of the influence of attitudes, subjective norms and perceived behaviour control have largely been presented. As mentioned above, this study is based on the social exchange theory (SET) tenets. In a nutshell, the SET proposes that social behaviour is moulded around an exchange process, the purpose of this

exchange being to maximise benefits and minimise costs. The notion of "social behavior as exchange" was first acknowledged by American sociologist George C. Homans in 1958 and since then this theory of social interaction has been widely used across many disciplines such as business, sociology, psychology and even economics. Social exchange "involves the principle that one person does another a favour and while there is a general expectation of some future return, its exact nature is definitely not stipulated in advance" (Blau, 1986:93). Although for Homans (1961), the dominant focus was on human behaviour and to explain the fundamental processes of social behaviour such as power, conformity, status and justice, SET sheds significant light into entrepreneurship today. There is a general consensus that social exchange, as understood in SET, involves a series of interactions that generate obligations among individuals (Emerson, 1976). Beyond the costs and the risks SET can be used to explain the development and continuation of relationships beyond what has been exchanged. In the context of entrepreneurship, it is logical to assume that entrepreneurial attitude can change due to positive values infused during social exchanges. As individuals exchange information, informally compete and cooperate on social issues, they solid their relationship, which can drive both of them towards a certain behaviour. In the words of Blau (1964:94), "the benefits involved in social exchange do not have an exact price in terms of a single quantitative medium of exchange", meaning social exchanges create enduring social patterns.

2.2 Conceptual model

Building on the social exchange theory tenets, this study explores how social interaction, measured in terms of information exchange, informal competitions and social cooperation, can influence entrepreneurial intention among university students at the Vaal University of Technology. The central hypothesis underlying this study is that social interaction needs to be promoted to increase entrepreneurial intention among university students. The direct relationships proposed in this study are represented in the conceptual model below.

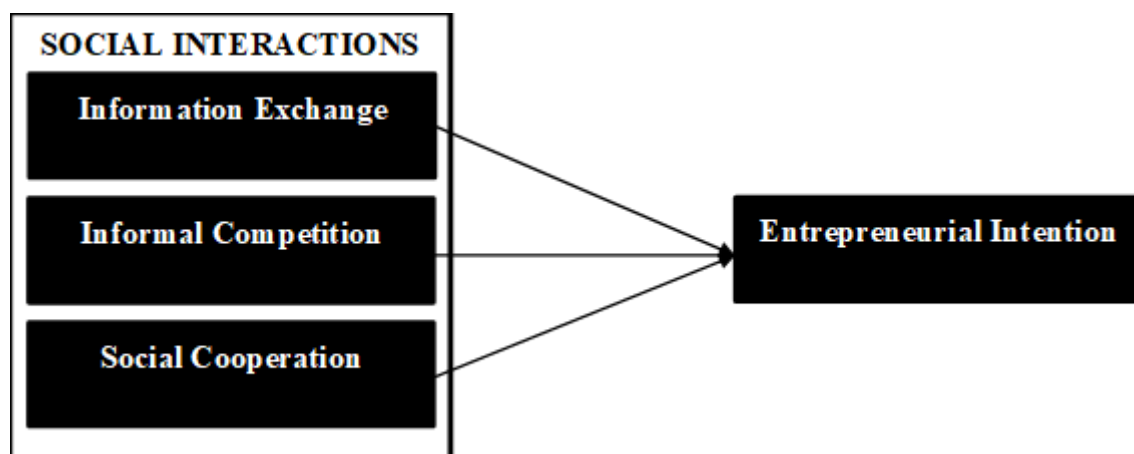

Figure 1: Conceptual model

2.3 Social interaction

In this study, social interaction relates to the direct or indirect exchange of physical and non-physical goods resulting in some level of social capital. In sociology, social interaction relates to the dynamic sequence of social actions between individuals or groups who modify their actions

and reactions due to the actions of their interaction partner(s). Social interactions can be differentiated into accidental, repeated, regular and regulated. According to Hong *et al.* (2004), these social interactions and peer effects affect several decisions, including the selection and financial assets. Woodward *et al.* (2018) believe that positive social interaction significantly affects individuals by decreasing stress among socioeconomically disadvantaged persons.

2.4 Entrepreneurial intention (EI)

EI has been defined as the orientation and willingness of an individual to start a new business and to accomplish this in future (Ridha & Wahyu, 2017) and this intention to start a new business has been central to the entrepreneurial literature. Generally, EI captures the cognitive state of individuals as they engage in decisions to create new businesses (Bullough *et al.*, 2014). In the literature, EI has been considered a critical factor that determines an individual's behaviour and is measured in terms of the desire or preference, self-prediction and intentional behaviour (Armitage & Conner, 2001).

2.5 Hypothesis Development

The above conceptual model follows the arguments and conclusions raised by Huang *et al.*, 2021) whose arguments, though not built on the same subconstructs, were that social interaction positively influences household entrepreneurship. Thus, the conceptual model mutates similar arguments around information exchange, informal competition and social cooperation as antecedents of entrepreneurial intention. Based on the arguments and empirical evidence, this study predicts the following hypothesis:

- H_1 There is a positive and significant relationship between information exchange and entrepreneurial intention among Vaal University students.
- H_2 There is a positive and significant relationship between informal competition and entrepreneurial intention among Vaal University students.
- H_3 There is a positive and significant relationship between social cooperation and entrepreneurial intention among Vaal University students.

3. METHODOLOGY

3.1 Research design

According to Ponto (2015), several methodological approaches can be used in research. The selection of a research design depends on the purpose of the research, the type of research questions to be answered and the available resources. This study adopted a cross-sectional descriptive survey design, using an online, self-report questionnaire based on a five-point Likert-type scale. This design was adopted because of its capacity to gather as much information as possible about a large population with some degree of accuracy (Rossi *et al.*, 2013). The descriptive survey design blends both quantitative and qualitative elements in order to provide relevant and accurate information. As such, it has also been regarded as a time-efficient research method, relevant in cases where people are at the centre of the research objective. Unlike other research designs like the experimental research, in a descriptive survey design, the researcher cannot manipulate any of the variables, but only observes and measures them.

3.2 Sampling method

This study was based on students at the Vaal University of Technology and in terms of sampling, the study adopted a probability sampling technique. In a quantitative study, probability sampling is regarded as appropriate because every member of the target population has a known chance of being included in the sample. Probability sampling methods include simple random sampling, systematic sampling, stratified sampling and cluster sampling, but this study chose simple random sampling. Out of an estimated 600 students enrolled for the Post Graduate Diploma in Logistics Management, Retail Business Management, Safety Management, Supply chain management and Retail Business Management in the first semester of 2022, the Google form link was sent to a randomly selected group of 300 students. As argued by Carland et al. (2001), this was done to ensure the appropriateness of participants and yield quality data.

3.3 Research instrument and data collection

To avert measurement errors and increase the validity and reliability of the research instrument, all scale items were adopted from previous studies. The research participants were required to rate their agreement or disagreement to a set of statements using a five-point Likert scale ranging from 1 ‘strongly disagree’ to 5 ‘strongly agree’. The outcome variable, EI, was measured using the scale developed and validated by Lin and Chen (2009), as moderated extensively by Karimi *et al.* (2016) and Miralles *et al.* (2016). The Social Interaction Self-Statement Test (SISST) (Glass, Merluzzi, Biever, & Larsen, 1982), the best-known cognitive endorsement procedure, which combines elements of a self-rating measure, was used in this study.

Table 1: Cronbach alphas for scales

| Construct | Cronbach alpha |
|--|----------------|
| EI Scale | 0.808 |
| The Social Interaction Self-Statement Test (SISST) | 0.756 |

A web survey was administered in this study, given the COVID-19 induced restrictions on movement and physical contact. In addition, web-based survey was preferred because unlike face-to-face and e-mail surveys, they do not require manual transfer of responses into a database, thereby saving on costs and reducing the amount of error biases (Dillman, 2007).

3.5 Data analysis

This study applied a structural equation modelling protocol using SmartPLS 3.3.9. According to Kock (2020), SEM allows researchers to build causal models with latent variables and over the years, partial least squares (PLS)-SEM methods have been increasingly popular. This view is supported by Ringle et al. (2020) who argue that PLS-SEM has become the key multivariate analysis technique for researchers, ensuring rigorous research and publication practices. As such, in validating the conceptual model and the hypotheses presented in Figure 1, PLS regression analysis has been adopted based on the questionnaire scale developed.

4. RESULTS AND DISCUSSION

Table 2: Background and demographic information of sample (N = 105)

| Items | Frequency | Percent | Items | Frequency | Percent |
|----------------------|-----------|---------|-----------------------|-----------|---------|
| Gender | | | Age | | |
| Male | 67 | 63.8% | Below 18 years | 0 | 0% |
| Female | 38 | 36.2% | 18-25 years | 81 | 77.1% |
| | | | 26-33 years | 21 | 20% |
| | | | 35 years & above | 3 | 2.9% |
| Race | | | Marital Status | | |
| Black | 104 | 99% | Single | 102 | 97.1% |
| White | 1 | 1% | Married | 3 | 2.9% |
| Coloured | 0 | 0% | | | |
| Year of Study | | | | | |
| First | 5 | 4.8% | Third | 13 | 12.4% |
| Second | 58 | 55.2% | Fourth | 29 | 27.6% |

From the results presented in Table 1, it can be observed that the majority of the respondents were male. The results show that the total number of male participants was 67 (63.8%) while female was 38 (36.2%). As expected among undergraduate students, the results indicate that the majority of the students (97.1%) are still single, while a meagre 2.9% are married. This has been the general trend among university students across South Africa and other countries. None of the respondents were below the age of 18 years and the majority fell into the 18-25 year category, which had 81 (77.1%). The second largest age group was the 26-33 year group with 21 (20%) participants. This was followed by the 35 years and above with 3 (2.9%).

4.1. Measurement scales' reliability and validity

Before one can test the hypothesis proposed in the conceptual model, it is important to test the validity and reliability of the measurement scale. Confirmatory factor analysis (CFA) was used to examine the construct validity and several indexes of the overall model fit were applied. The instrument's reliability was measured in terms of the Cronbach alpha and estimated loading factors (LF) of all the questionnaires (items). The composite reliability (CR) and the average variance extracted (AVE) of each construct were used to measure validity (Fornell & Larker 1981; Anderson & Gerbing 1988). Table 2 presents the scores for CR, Cronbach's alpha (α) and AVE obtained from this study.

Table 2: Descriptive statistics and confirmatory factor analysis (N = 105)

| Constructs and factors | Mean | S.D. | Factor loading | CR | AVE |
|--|-------|-------|----------------|-------------|-------------|
| Information exchange (Cronbach's alpha = .747) | | | | .873 | .635 |
| I frequently share business material, papers and notes with other students in my university | 4.847 | 1.144 | .887 | | |
| I frequently share entrepreneurship motivational speeches and advice based on my experience with other students in my university. | 4.720 | 1.141 | .669 | | |
| I always contribute ideas and thoughts to formal and informal discussions on business incubation with other students | 4.855 | 1.135 | .814 | | |
| I have participated in several online and face to face community interactions to share information and knowledge on entrepreneurship and business skills | 4.837 | 1.110 | .801 | | |

| Constructs and factors | Mean | S.D. | Factor loading | CR | AVE |
|--|-------|-------|----------------|-------------|-------------|
| Informal competition (Cronbach's alpha = .776) | | | | .880 | .646 |
| There is a general sense of materialistic competition among my friends and peers. | 4.873 | 1.079 | .760 | | |
| I generally feel I need to keep pace with my peers in terms of financial growth | 4.880 | 1.104 | .819 | | |
| There is a general tendency among my peers to compete for resources. | 5.094 | 1.195 | .821 | | |
| I always work to be the first to achieve a certain goal than any of my friends or peers. | 4.753 | 1.168 | .814 | | |
| Social cooperation (Cronbach's alpha = .831) | | | | .887 | .662 |
| I have collaborated with my friends or peers on several projects. | 4.597 | .963 | .894 | | |
| It feels good working together to achieve results or people helping each other out to achieve a common goal. | 4.606 | 1.017 | .795 | | |
| I have never ignored a friend or peer when they are facing a social or financial dilemma. | 4.563 | .966 | .805 | | |
| There are always mutual benefits from cooperating with other students within the university and community. | 4.511 | 1.110 | .755 | | |
| Entrepreneurial intention (Cronbach's alpha = .857) | | | | .897 | .687 |
| I am determined to create a firm in the future. | 4.695 | 1.109 | .878 | | |
| It's a good idea to start saving money to start a business now. | 5.049 | 1.047 | .756 | | |
| It is an investment to spend time learning about starting a firm. | 4.882 | 1.049 | .794 | | |
| My greatest achievement will be to start and run my own business. | 4.783 | 1.099 | .880 | | |

In SEM-based studies, the lowest acceptable factor loading is 0.500 (Borroso et al. 2010), composite reliability (CR) of each construct is 0.5 (Hair et al. 2011) and AVE is 0.5 (Urbach & Ahlemann 2011). Regarding the Cronbach's alpha, the general rule is that for reliability to be conferred, the alpha values for a construct should be above 0.700 and the results presented show that all the α scores were above the threshold.

Table 3: Discriminant validity of the model's constructs on Fornell-Larcker

| Construct | AVE | IE | IC | SC | EI |
|-----------|------|-------------|-------------|-------------|-------------|
| IE | .635 | .797 | | | |
| IC | .646 | .412 | .804 | | |
| SC | .662 | .454 | .451 | .814 | |
| EI | .687 | .344 | .521 | .442 | .829 |

NOTE: The elements of the diagonal (bold) are the square root of the variance shared between the constructs and their measures (AVE). The values below the diagonal are the correlations between the constructs.

Table 2 showed that the lowest Cronbach alpha was .747, showing the high internal consistency (Zhang, Li, Liu, & Ruan, 2019). The results in Table 3 show that the square roots of the AVE were all greater than the inter construct correlations. As such, reliability and validity were achieved. Confirmatory factor analysis (CFA) was used to further examine the goodness of fit of the model and the model fit the data well ($p < .001$; $\chi^2/df = 2.156$; CFI = .937; IFI = .929; TLI = .927; NFI = .916; RFI = .904; AGFI = .859; and RMSEA = .570). Thus, the CFA assessment indicated the structural models and is suited for hypothesis testing

4.2 Hypothetical test

This study used structural equation modelling (SEM) in AMOS 20.0 to examine the mediating and moderating effects. SEM is a multivariate statistical analysis and multiple variables in this study can be analysed simultaneously (Tho, 2018). Further, it integrates two statistical methods: factor analysis and path analysis. SEM can deal with latent variables and indicators concurrently and simultaneously analyse the direct effect, indirect effect and over model fit (Liu, 2018). Besides, the model allows measurement errors in independent and dependent variables, while traditional analysis is difficult to solve.

Table 4: Hypothesis Testing

| Hypothesis | Direct Effect | t-Value | p Value | Decision |
|------------|---------------|---------|---------|-----------|
| IE→EI | .412 | 12.893 | .000 | Supported |
| IC→EI | .280 | 1.458 | .000 | Supported |
| SC→EI | .256 | 2.568 | .000 | Supported |

The results provided in Table 4 indicate that all the three hypotheses were supported at $p < 0.05$. H_1 proposed that there is a positive and significant relationship between information exchange and entrepreneurial intention and a path coefficient of .412 was obtained, confirming the proposition. Also, H_2 stated that there is a positive and significant relationship between informal competition and entrepreneurial intention and the result of a path coefficient of .280 is confirmation to that. Lastly, H_3 indicated that there is a positive and significant relationship between social cooperation and entrepreneurial intention. The results indicate a path coefficient of .256 at $p < 0.05$; hence, the hypothesis is supported.

The results imply that in order to influence entrepreneurial intention among university students, it is important that institutions and communities cultivate social interactions. As students exchange more information, compete informally among each other and cooperate at social levels, they are able to nurture their intention to start businesses. From the results it can be noted that information exchange has the largest influence of entrepreneurial intention and this is one variable that organisations should focus on.

5. CONCLUSION

The confirmation of the hypotheses made in this study allows for drawing several conclusions of interest in relation to the factors that influence entrepreneurial intention among university students

in South Africa, particularly in the Vaal University of Technology. Entrepreneurship has been an area of concern to institutions across South Africa and these conclusions must be made. Information exchange among students is a critical factor in the build-up to stronger entrepreneurial intention among South African students. Although other factors such as attitude have always been prioritised in discussions around intention, it has emerged that information exchange equally merits consideration. It is therefore important that universities, social clubs and communities, organise workshops and seminars on entrepreneurship so that the students are afforded opportunities to exchange information. There is need for students to be afforded several opportunities to interact and exchange information. Of note is the fact that informal competitions be encouraged among students. In this regard, it is important that universities organise entrepreneurial competitions within the university to encourage the spirit of competition. Lastly, entrepreneurial training can be used as a tool to enhance social cooperation. This is because one of the conclusions that can be reached from this study is that social cooperation is an important antecedent of entrepreneurial intention.

SSIRC 2022-070

A CRITICAL INVESTIGATION OF TEACHING PRACTICE MODELS IN FOUNDATION PHASE TEACHER TRAINING IN SOUTH AFRICA

R. Lemmer

Department of Education, Aros, Pretoria, South Africa

S.G. Le Roux

University of South Africa, Pretoria, South Africa

ABSTRACT

Teaching practice as a requirement for all undergraduate teacher qualifications in South Africa has not been very successful in terms of raising the quality of initial teacher education. Teaching practice outcomes are influenced by various contextual factors in the South African landscape. Guidelines provided by the South African policy framework (DHET 2018) only suggest time frames for teaching practice and vaguely mention a structured mentorship programme and proper supervision as a requirement, without providing any formal structure or guideline to ensure that this is possible. The purpose of this study was to investigate the shortcomings of teaching practice models with the aim to propose suggestions to improve teaching students' practical preparation. As a theoretical framework, this investigative case study drew from the human capital theory as well as the sociocultural theory (Tomer 2016; Vygotsky 1978). Adopting a qualitative research design, this case study identified four South African higher education institutions that train foundation phase teachers through an open distance learning approach. Four primary schools in the Gauteng province were also identified through random sampling. Data were collected through individual semi-structured interviews with lecturers, school principals and mentor teachers. In addition, questionnaires were used to collect data from students who were doing teaching practice at the four participating schools. Based on the fact that the findings have confirmed the undeniable value of teaching practice and the importance of proper mentoring, the recommendations focus on suggestions about how the policy framework could provide for formal internships and proper induction programmes for student teachers, as well as the introduction of teaching schools or schools of professional practice. The findings of this study have an implication on how the South African schooling system and institutions of higher education need to collaborate to create a policy framework that will provide for formal internship programmes of student teachers. Such a policy framework will regulate internships for students registered with distance education institutions as well as traditional residential universities.

Keywords: Internship, mentorship, professional practice schools, teacher assistants, teaching practice, work-integrated learning.

1. INTRODUCTION

Around the world, teaching practice forms an integral part of the undergraduate training of student teachers. The purpose of practical teaching is to give student teachers the opportunity to experience the implementation of theoretical knowledge in action and to provide students with an opportunity to practise teaching skills in a safe environment under the guidance of an experienced mentor. Unfortunately, the education landscape in South Africa is still characterised by inequalities nearly

26 years after the transition to a new democratic system. The Parliamentary monitoring group in 2015 (Parliamentary Monitoring Group 2015), reported that as many as 80% of South African schools are dysfunctional. The implication is that teaching practice may not add much value when student teachers are placed in dysfunctional schools and that the quality of newly qualified teachers may be negatively impacted as a consequence. There is, therefore, a great need for a teaching practice model with a set of uniform criteria that will enhance the quality of teacher training.

Teaching practice, also considered vocational focused education or work-integrated learning (WIL), includes both the theoretical classroom-based, and work-based forms of learning (Winberg, Engel-Hills, Garraway & Jacobs 2011). In South Africa, the policy document Minimum Requirements for Teacher Education Qualification (MRTEQ) (Department of Higher Education and Training) (DHET 2015)), provides the framework for initial teacher training programmes. According to MRTEQ's guidelines, school-based teaching practice is a form of work-integrated learning (WIL), and supervision and controlled teaching practice are requirements for the Bachelor of Education (B.Ed).

According to MRTEQ, the following guidelines for WIL must be met:

- It must be distributed over the course of the academic programme.
- It must take place in block periods of which the duration may vary.
- There should be a guarantee of good mentorship, placement in a suitable school and formal assessment of the practical component.
- WIL must take place in functional schools.
- It is the task and responsibility of every educational institution to set minimum standards that define competence (DHET 2015).

Qualities such as good organisation and management, flexibility, resilience, high quality of teaching and learning, high expectations and good discipline are prerequisites in schools where students are placed for teaching practice. If this is not in place, it leaves a question about the quality of mentoring that student teachers will be exposed to. In an education landscape where approximately 80% of South African schools are considered to be dysfunctional (Parliamentary Monitoring Group 2015), placement in affluent and popular schools is in high demand. Since distance learning students are spread across the country, they are also compelled to do teaching practice at their nearest school, regardless of the quality of teaching and learning at the school.

For the purpose of this study, teaching practice programmes of institutions of higher learning that train foundation phase teachers via an open distance learning approach, were explored. This decision is based on the fact that almost half of the nation's teachers are delivered through South Africa's largest distance learning institution, the University of South Africa (Unisa 2019). My interest in this study was sparked by the fact that I am the programme coordinator for teaching practice at a private distance learning institution and I was also driven by a desire to improve teaching practice experiences and the quality of teacher training of our students.

Based on the preceding background, the following research question was formulated:

What criteria should teaching practice models in the South African context meet to provide quality practical experience to students studying foundation phase teaching through open distance learning?

The aim of the study was to investigate the shortcomings of teaching practice models currently employed by open distance education institutions in South Africa, with the aim to propose suggestions to improve teaching students' practical preparation and, subsequently, the quality of newly qualified teaching students being delivered into the schooling system. I also aimed to explore, evaluate, and describe the type of teacher as well as the kind of environment essential for quality education. This information was evaluated and described against the challenges that schools and students experience during teaching practice. Teaching practice, as currently offered by open distance learning institutions in South Africa, has been interpreted using various theoretical frameworks and models that underpin teaching practice, with careful consideration of the South African context.

2. LITERATURE REVIEW

2.1 Theoretical framework

This study is grounded on the human capital theory of Smith (1776), Olaniyan and Okemakinde (2008), as well as the sociocultural theory of Lev Vygotsky (1978). The human capital theory originated in the 1700s, when Smith (1776) claimed that education forms the basis of human capital in every sphere of society and enables and sustains economic growth. Smith (1776) proposed that the acquisition of valuable skills and knowledge increase individual human capital, while at the same time increasing the overall wealth of the nation concerned. Kupe (2019) agrees that universities worldwide and in South Africa are expected to contribute to the advancement and development of their societies by investing in their graduates. In this regard, government, the private sector, and students themselves invest in obtaining human capital through, for example, appropriate university education of a high standard.

Tan (2014) also agrees with the tenets of the human capital theory in believing that education and training are considered the source of economic growth. Human capital theory argues that man's cognitive abilities are enhanced through education and training, resulting in increased productivity and higher incomes (Tomer, 2016; Olssen, Codd & O'Neill 2004). Quality training not only contributes to the physical and financial benefit of the student, but also to the skills demand of the school and community. High-quality training increases the number of graduates, thereby boosting the economy and attracting development investments. Higher levels of training and training proficiency also stimulate technological advances, which are employed in the classroom to increase quality education. Thus, a cycle of progress and growth is created to the benefit of individuals and the economy.

The use of technology and technological skills in teaching practice also has a significant impact on the acquisition of new knowledge. In the fourth industrial revolution, technological knowledge and skills increase occupational readiness and employability. Electronic searches for knowledge and the online study of skills through videos shorten the time spent learning and promote economic growth. In a technological world with internet access and quality education research data, education students gain access to a variety of educational practices.

On the other hand, Vygotsky's sociocultural theory (Vygotsky 1978) proposes mentoring as a critical component for new skills to be acquired. Teaching practice implies that the student (mentee) should be guided and supported by a more experienced person (mentor) to obtain the

relevant practical skills. Teaching practice is further influenced by Vygotsky's concept of scaffolding, where students learn to master practical skills in a progressive way, starting with observation in year one, moving to co-teaching until the student is finally in year four and ready to plan and present a lesson solo.

Student guidance and support should take place in what Vygotsky refers to as the zone of proximal development. This involves guiding the inexperienced student by identifying what they can do by themselves and what they need help and assistance with. Although Vygotsky's sociocultural theory primarily explains how young children learn, the underlying principles can also be applied to adults, and for the purposes of this study, to students.

3. METHODOLOGY

3.1 Research design

A case study design has been identified as the most appropriate research design as it allowed me to "listen" to the participants, whom I considered to be rich in data and to learn from their lived experiences (Braun & Clarke 2006). According to Creswell (2018) and Denzin and Lincoln (2013), a requirement of qualitative research is that it takes place in the natural world. As knowledge was gained primarily by "engaging" with reality, interpretivism was identified as the philosophical paradigm underpinning this study.

In this study, the emphasis was on an inductive way of working, where different teaching practice models and programmes were studied with the aim to identify shortcomings and best practices. International models of teaching practice were compared with the teaching practice models of the four identified South African teacher training institutions that train teachers through a distance learning approach. The aim was to identify possible patterns and to make recommendations that can be of value on a larger scale (Joubert, Hartell & Lombard 2016).

3.2 Sampling method

According to Mouton (2011), the target population is the group to be used in the research study, from which conclusions can be drawn. This study identified the target population as institutions of higher education that train foundation phase student teachers through an open distance learning approach. The schools that were invited to participate in the study also had to be representative of the country's demographics, diverse cultures, and languages.

The criteria for inclusion of the higher education and training institutions were as follows:

- • They must be an accredited educational institution in South Africa.
- • The B.Ed Foundation Phase programmes must be accredited.
- • Teaching and learning must be offered through a distance learning approach.

After the five institutions were identified, a lecturer involved with teaching practice at each institution was purposefully selected and invited to participate in the study.

Identification of the participating schools:

Four schools were randomly identified from a database of schools in the Gauteng province.

Participants in the identified schools:

- The principal and four mentor teachers from each participating school were purposefully selected because they were considered to be rich in data (Creswell 2018). The four mentor teachers at the participating schools were identified by the principal and were invited to participate in the study.
- Thirty teaching students who were doing teaching practice at any of the participating schools and who were enrolled at any of the four identified distance learning institutions were invited to participate in the study.

3.3 Research instruments

Semi-structured individual interviews were used to collect data from the lecturers, principals, and the mentor teachers. Questionnaires were used to collect data from the participating students who met the criteria of being enrolled at any of the four identified institutions.

3.4 Data collection

After all participants gave consent to participate in the study, interviews were scheduled at a time most convenient for them. Through open questions, the participants were prompted to share their own experiences, knowledge and insights. The nature of the semi-structured individual interviews also allowed for the observation of non-verbatim data, such as sighs or long silences (Maree 2020). With the permission of the participants, the interviews were recorded to be transcribed later. Biographical data such as age and gender were captured, and pseudonyms were used to ensure confidentiality.

Because the students were the larger group, questionnaires were handed out to those participating. The questionnaire questions differed from the interview questions in that they were more focused on the students' experience of teaching practice. The questionnaires had the advantage that students could complete them later, in their own time. They also allowed students to spend more time with some of the more difficult questions, without the discomfort of having to respond on the spot. The questionnaires also allowed for anonymity and therefore encouraged honest responses.

3.5 Data analysis

The interviews were transcribed and stored electronically. A master list was compiled to be used to verify and confirm the reliability of the encrypted data. Thereafter, the data that was collected through the interviews and questionnaires were sorted and labelled with the assistance of the ATLAS.ti, a computer programme considered one of the most powerful tools for qualitative research. Then the groups of interviews and questionnaires were analysed and interpreted through coding. After multiple readings and note-making, recurring themes and categories were identified. Diagrams were used to point out and summarise relationships between groups of participants.

In Table 1 below, the themes, categories, and codes that were identified, are outlined.

Table 1: Overview of themes, categories, and codes.

| Research questions | Themes | Categories | Codes |
|--|---|--|---|
| What requirements should teaching practice models meet to deliver the type of teacher envisaged by the South African education system? | Models underpinning teaching practice and theoretical frameworks | Requirements that underpin teaching practice | Scaffolding Mentorship Apprenticeship (Internship) Functioning schools (Good school management) Quality education training Partnerships |
| Do the current teaching practice models meet the need to ensure quality education? | The type of teacher envisaged to deliver quality education within the South African education landscape | Teaching practice within the South African education landscape | Problems in basic education affecting teaching practice The role of higher education Requirements for undergraduate teacher training programmes Methods for delivery Features of practice-based education |
| What factors affect the workability of teaching practice models currently used to prepare student teachers for the foundation phase? | Factors affecting the workability of teaching practice models | Factors affecting teaching practice | Partnerships between universities and schools Mentorship and mentoring Placement and time of practical teaching Assessment of skills during practical teaching |

4. RESULTS AND DISCUSSION

A confirmation of the value of teaching practice was the first theme to emerge. The data collected from the interviews and questionnaires unequivocally confirmed the value of practical teaching. Participants confirmed that student teachers were given the opportunity to experience the philosophical and pedagogical actions of teaching in action during teaching practice. Teaching practice further provided student teachers the opportunity to learn and practice skills in interpersonal relationships and conflict management. It also has the value of reducing a reality shock as is often experienced by many teachers entering the teaching profession. Some participants reported the value of exchange agreements between schools, providing teacher assistants employed in schools an opportunity to gain valuable experience in more than one school

The second theme that emerged from the participants' feedback confirmed the importance of good mentorship and a need for formal mentoring training. This was important to note, as formal mentoring training is not a requirement for one to act as a mentor to students in schools. Only two of the four universities that participated in the study offered mentor training to the schools where their students are placed. This finding confirms the need for accredited mentor training programmes, either through universities or through accredited private service providers.

The third theme that emerged was around the timing and duration of teaching practice cycles. From the feedback, it became clear that there was no ideal time for teaching practice, but a need for better communication and coordination between the schools and universities around student placement was raised. Participants also agreed that more time spent in schools will only be beneficial if students spend that time in functional schools. This was confirmed by students who were appointed as teacher assistants. They had the opportunity of working in schools throughout the year and were of the opinion that they were better prepared than students who only did a few

weeks of teaching practice each year. Unfortunately, it is only the more “wealthier” schools that have the additional funding to appoint students as teacher assistants.

The fourth theme that emerged was around the teaching practice portfolios and curricula requirements. These varied greatly between institutions, and this probably explains the difference in the quality of teaching practice between the participating institutions. Possible reasons for this were identified as follows:

- a) Each university, in consultation with the directives provided by the Council on Higher Education and the South African Qualifications Authority (SAQA), compiles its own learning programmes.
- b) Each university structures the practical teaching activities and portfolios differently, according to its own needs.

Some of the challenges that were reported are as follows:

- The portfolios and activities are not aligned with the annual teaching plan as prescribed by the Curriculum and Assessment Policy Statements. This means that students are often required to prepare and present a lesson based on a topic that was already covered or will only be covered later in the year.
- The mentor teachers often expect the students to teach the scripted lessons that are provided by their provincial department of education. These scripted lessons often vary from one province to the next and from one district to the other. Scripted lessons reduce a teacher to an end-user of a pre-prepared product and does not allow for any creativity on the part of the teacher or allow the teacher to respond to the needs of her unique group of students.
- Some students voiced their frustrations about the extra expenses brought about by having to buy material to make teaching resources, especially in schools where teaching and learning resources were limited. Students also complained about their workload during teaching practice, as they had to compile teaching practice portfolios in addition to their regular assignments.

The last theme that emerged was around a formal structure that will allow for collaboration between higher education institutions and schools and that will expand the pool of functional schools being used for teaching practice. Such a formal structure will also prevent schools located near universities being overused and build capacity in more rural provinces and areas. Such identified schools could become an entry point and a developmental path for young people in rural areas wanting to choose education as a career.

5. RECOMMENDATIONS

Figure 1 provides a visual representation of the challenges that were identified as well as recommendations to address these challenges.

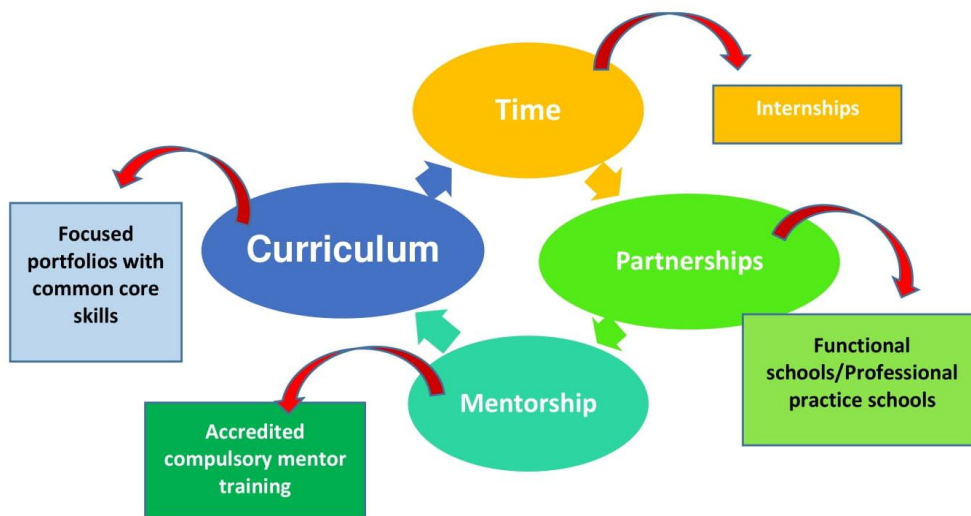

Figure 1: Recommendations to address challenges in teaching practice at distance learning institutions in SA

5.1 Internships

Although work-integrated learning (WIL) is a requirement for teacher qualification programmes, the current South African policy framework does not provide for formal internships in education. Similar to the South African Council for Health Professions (SACHP), which requires a compulsory year of internship for students graduating as doctors, occupational speech and physiotherapists, pharmacists, and so on, a formal one-year internship should be made compulsory for graduating teachers. Such a proposal implies that student teachers will only qualify for registration as a teacher with the South African Council for Educators (SACE) after having completed the internship year.

Such an internship model would also give contact students the benefit that distance learning students enjoy, of being appointed as teaching assistants. Another advantage of such an internship model is that rural schools could also be strengthened with human resource capital. Cameroon, which already follows such an internship model (Endeley 2014), can be used as a source for research in this regard. An internship model can do much to reduce teachers' workload, especially where an unfavourable learner-to-teacher relationship impacts negatively on quality education. Such a proposed internship model would require a restructuring of the budget allocated to basic education.

5.2 Compulsory accredited mentoring programmes

Although accredited mentoring programmes do exist, they are mainly offered by private providers, and accredited mentoring qualifications are not a formal requirement to serve as a mentor teacher. Apart from induction programmes that schools have, to welcome teacher students, the quality of mentoring experiences in teaching practice vary greatly. Formal compulsory mentor training could be offered as a short learning programme or skills programme within the Sector Education and Training Authority (SETA) framework. The South African Council for Educators already has a points system in place to promote continuing professional development (CDP). Such a requirement

would allow for a recognised designation for mentor teachers, as promotion opportunities within the education system are limited.

5.3 Focused portfolios with common core skills

Although higher education institutions are autonomous, and each is responsible for the content of its own learning programmes, there should be a common set of core skills that need to be assessed through teaching practice portfolios. A proposed forum between universities, the national departments of basic education, the nine provincial education departments and SACE could serve as a platform to facilitate a greater partnership between all role-players to align common goals and outcomes that will improve the quality of teacher training in South Africa.

Although the minimum competencies expected of newly qualified teachers are outlined in the new 'Minimum Requirements for Teacher Education Qualification' (MRTEQ) (DHET 2018), all role-players must ensure that the basic competencies of a teacher are included in the portfolio activities. The focus should not only be on how to plan and present a lesson, but also include soft skills such as adherence to the school's code of conduct, self-discipline, dealing with discipline of learners, knowing school policies, how to fill in attendance registers, attending subject and phase meetings, setting up assessments, marking and writing of progress reports, and attending parent-teacher meetings, to name but a few.

5.4 Professional practice schools

Although professional practice schools are common internationally, it is still a much unknown concept in South Africa. Unlike school laboratories sponsored by universities and operating independently, professional practice schools exist as part of the public schooling system and serve the public schooling system in general. Their aim is to provide a context for rethinking and reinventing schools for building and sustaining best practice, to contribute to initial teacher education and training and induction into the profession, and to provide for the continuing and professional growth of in-service teachers. It is envisioned that professional practice schools will provide the collective and collaborative structure to achieve quality education. Professional practice schools can provide a variety of learning environments for students, without compromising on quality. Identifying professional practice schools would ensure that schools across the country could be identified and developed with the aim of providing quality practical training to student teachers.

A proposed policy framework may need to be developed to provide requirements and guidelines of such identified schools, and to define the roles and responsibilities of the various role-players.

6. CONCLUSION

The aim of this study was to highlight some of the shortcomings, but also some of the best practices in teaching practice models used by participating distance learning institutions in South Africa. The study also tried to explain why the quality of teaching practice varies from institution to institution. The recommendations provided by the MRTEQ policy document have been found insufficient to provide a workable structure to ensure quality teaching practice. Recommendations emanating from this study offer practical and long-term proposals on how the existing guidelines can be strengthened to ensure quality practical teaching. The recommendations provide practical

solutions on how to provide for formal accredited mentor training, propose a solution for internships within the education sector, and how to address the need for a focused curriculum with clear assessment requirements. It further advocates for the identification of functional schools to become training schools or professional practice schools.

The findings of this study have a huge implication on how the South African schooling system and institutions of higher education need to collaborate to create a policy framework that will provide for formal internship programmes of student teachers. Such a policy framework will regulate internships for students registered with distance education institutions as well as traditional residential universities and ensure an improvement in the quality of initial teacher training across all types of institutions. Teacher training institutions from developing countries with a similar context to that of South Africa, may also benefit from this study.

ABSTRACT

The aim of this study was to ‘explore the effects of urbanisation on the availability of medicinal plants (Red data species) in the Malamulele area of Limpopo Province, South Africa,’ thus, there are several negative factors that contribute to the survival of these plants. These include the loss of demarcated to habitat, increase of human population, urbanisation and threats brought by climate change, amongst others. This study applied the exploratory research design in order to achieve its aim. Thirty-six respondents were selected through purposive sampling to participate in the study. In-depth semi-structured interviews were employed for data collections. For data analysis; the Spiral Data Analysis was adopted to organise data aligned to the objectives of this study, while identifying relevant themes. The findings of this study indicates that the availability of medicinal plants in the study area are threatened by the factors mentioned above. The data that was collected indicates that all the participants hold the view that urbanisation poses a great threat to the survival of indigenous medical plants. Furthermore, they contend that available conservation methods to prevent indigenous medical plants from possible extinctions are either not implemented properly or are neglected.

Therefore, the discovered rapid loss of these plants might affect future preservations and protections. The expansion of the Malamulele city due to urbanisation contributes to the witnessed decreases of natural resources (Medicinal plants included). In conclusion, although majority of Malamulele residents still rely heavily on the use of medicinal plants for their primary health care because of their medicinal and therapeutic properties. These plants are also an important food source for the residents of Malamulele. These residents are, however, often unable to protect the plants from the threats posed by urbanisation. Necessary conservation methods should be looked at, as Malamulele residents heavily rely on the positive use of medicinal plants. It is also recommended that indigenous people and the Collins Chabane Local Municipality (CCLM) should take actions to protect these plants from extinctions.

Keywords: Medicinal plants Conservation, Effects, Extinction, Limpopo Province, Malamulele area, Urbanisation, South Africa.

1. INTRODUCTION

Indigenous people around the world possess an increased ability to influence the management and conservation of biodiversity (Steenkamp, 2002). Although the people who have acquired this indigenous knowledge are made to be reliant on the use of western pharmaceutical methods of herbal and medicinal activities (Hassan, 2012), they prefer to use their indigenous traditional practices. Medicinal plants are important to humanity and continue to be used worldwide as a source of food and basic healthcare (Hassan, 2012). Some of the medicinal plants are recommended because of their therapeutic values (Hassan, 2012). It is necessary to have good management and conservation methods of plant species for their continued availability (Stern, Bidlack, Jansky & Uno, 2000). However, the improper management of biodiversity leads to the destruction of resources, which in turn is essential for the survival of people (Steenkamp, 2002).

Several factors contribute to the extinction of medicinal plants. These include habitat loss, population increase, urbanisation and threats brought by climate change. Furthermore, there is a promising future for the use medicinal plants because there is an estimated number of around 500 000 of existing plants all over the world. Although most of them are known for their medical characteristics, some of them have not yet been fully investigated. These medicinal plants may contain ingredients that could be significant in the treatment of present or future diseases. They are often used for synergic medicine, support of official medicine and preventive medicine, among others (Hassan, Hadi, Kassim & Al-Hassany, 2012). According to Keskin (2018), there is approximately 1,000,000 plant species in the world, and almost half of these have been identified and named. These plants should be preserved and protected unlike with most animals (Raven, 2021). For example, there are over 115,000 plant species that have been identified and named around the world, over a quarter of the total estimated number, currently in cultivation in botanical gardens (Raven, 2021).

To address the negative factors such as urbanisation, habitat loss and population increase on medicinal plants, knowledge and skills about the management of biodiversity are required (Martin, 1995). Like in many other parts of the world, South Africa's indigenous plant systems are depleting and good management, as well as investing in conservation of biodiversity is necessary. This initiative can improve the preservation and protection of medicinal plants across the country (Mabogo, 1990; Rankoana, 2000, and Rankoana 2001). Subsequently, as in many other places of South Africa, the area of Malamulele is also facing the depletion of medicinal plants. Malamulele is located in the CCLM within the District of Vhembe in Limpopo Province of South Africa. Medicinal plants in this area are tarnished by various factors such as deforestation, illegal harvesting and over harvesting,-amongst others. Therefore, there is a need to assess the extent of damage that is caused by these kinds of actions to the existence of medicinal plants using recognised and acceptable methods. One of these methods is to control and cultivate these medicinal plants on a commercial level in order to ensure their sustainable supply for future use.

Medicinal plants are usually used and traded in their raw nature with less to no worth addition. This limits the financial benefit that is accumulated by beneficiaries and reflects on the limited bio-prospecting work being carried out on the plant species (Shumba, Carlson, Kojwang, Sibanda, Masuka & Moyom, 2009). Brower (2008) highlights that medicinal plants serve as essential anchors of an ecosystem, and if they are to disappear, symbiotic organisms and marine life will be severely affected. Since factors such as urbanisation impose a great threat on the availability of

medicinal plants, the future discoveries of the features of these plants are most likely to be affected by the rapid loss of the plant population. Most of the species are classified to be Least Concern (Brower, 2008). These plant species have been characterised by the International Union for Conservation of Nature. These plants may in the near future be extinct. As a result, making regional risk assessments even in data-sparse countries can aid in the planning of conservation management, and for urgent considerations (Kaky & Gilbert, 2019).

The International Union for Conservation of Nature Red Data List remains one of the highly recommended indicator in all the available conservation pointers; however, most of the developing countries have less or limited access to enough data with regards to making assessments (Kaky & Gilbert, 2019). Therefore, there is a necessity to find sustainable ways of harvesting medicinal plants that are found in the wild, as well as to educate locals on better and progressive measures to gather these plants in proper collection methods and train the people on how to uproot medicinal plants and grow them in a safe space (Shinwari, 2010).

Operationally, the Vhembe District Municipality Integrated Development Plan Review (2019/2020) defines the 'biosphere reserve' as a category that accommodates habitat to a number of plant species (Those vulnerable to a point of facing extinction included). The Biodiversity of Vhembe District considers rural communities as priorities. As a result, shelter, food; fuel wood, and medicinal plants are provided (Vhembe District Municipality Integrated Development Plan Review, 2019/2020). Du Toit (2015) cautions that as rural population decreases and cities expand, natural resources, i.e., plants, are threatened in that they are cleared to make way for urbanisation. This trend is also common in the area around Malamulele and has also been observed in the selected villages of '*Roodhuis, Mphambo, Xigalo, Xitlhelani, Madonsi, and Mavambe,*' as found in the CCLM. This study thus aims to understand the effects of urbanisation on medicinal plants with the focus placed on the selected villages under CCLM. This will also allow for the documentation and offering of empirical evidence on this subject, further leading to suggestive conservation and preservation measures.

2. LITERATURE REVIEW

2.1 The effects of urbanisation of medicinal plants

Several researchers (Du Toit, 2015; McKinney, 2008; Magoro, 2008, Wang, Li, Kuang, He, Chen, Huang and Łowicki, 2020, McKinney, 2006, and Van Wyk *et al.* 2002) have documented the effects of urbanisation on species scarcity. Most of these researchers mention that urbanisation is considered as one of the major contributory factors that lead to the extinction of medicinal plants. Based on geographical settings, urbanisation can either grow or decline the richness of rural species (Czech *et al.* 2000). Plants that are frequently used for the purposes of health care needs are largely affected by urbanisation. This subsequently causes scarcity of these plants, leading to extinction (McKinney, 2008).

In order to determine the effects of urbanisation on species richness, McKinney (2008) reviewed 105 types of species. His study concluded that approximately 65% of these plants showed to be increasing in species richness, based on moderate urbanisation. The other remaining 35% is affected by non-development factors, such as climate change. Bolund and Hunhammar (1999) share that biodiversity is the main output for urban environments and improvements. Urban

biodiversity aims to instil knowledge about the effects that urban populations have on medicinal plants as well as on the importance of protection and conservation of nature (Medicinal plants included). This involves the management of medicinal plants that are already facing extinction (Miller & Hobbs, 2002).

Furthermore, the trials that effect biodiversity should assist to better understand the growth of urbanisation and conservation methods (McKinney, 2008). This should be exercised while taking into account the effects that urbanisation have on medicinal plants availability and extinction, prioritising the complexities that surrounds the nature of the use of urban land and medicinal plants availability should be clear that it accommodates local rural biodiversity and related inspirations (Czech *et al.* 2002; and McKinney, 2006).

Mander *et al.* (2007) reveal that the African Health Care System of South Africa has always been dependent of medicinal plants. Due to the increase in urbanisation, the demand of medicinal plants also increases (Williams *et al.* 2013). Knowledge that people have about medicinal plants, such as the recognition, naming, use, and management of species, can be affected by urbanisation (Arjona-García *et al.* 2021). Importantly, the possible use of the Indigenous Knowledge Systems (IKSs) on medicinal plants should be adequately exercised, as South African rural citizens currently have unlimited access to the western health care services, as provided by the National government and private entities. Moreover, the loss of this indigenous knowledge and neglect of medicinal plants could be attributed to a decrease that is seen in areas of agriculture, agroforestry, and forest, since urbanisation reduces the areas in which medicinal plant are collected and destroys the existence of medicinal plants (Arjona-García *et al.* 2021). The trade of medicinal plants is currently greater than it was in the past because of the important indigenous values associated with medicinal plants, the high human population growth and rapid urbanisation (Wiersum *et al.* 2006).

2.2. Identifications of medicinal plants facing scarcity

Most of the people who reside in sub-Saharan Africa rely on plants for primary health services. Medicinal plants are considered a major single category of plants (Ganeshaiyah *et al.* 1998). Approximately 30 000 species fall under this group globally, and about 33% are said to be trees (Ganeshaiyah *et al.* 1998). From 6 377 plant species used in ‘Tropical Africa’, about 2 074 have medicinal applications. However, this is not only regarded to be their main use, because only 1 975 are primarily used for medical purposes (Magoro, 2008). From a cultural perspective, the healing and spiritual applications of plants are embraced. Nevertheless, Western medicine has disturbed the work of ‘African Traditional Health Practitioners (THPs) and South Africa’s Traditional Healing Folklore; although it is reported that this is diminishing.’ It is also hinted that the THPs find it difficult to access medicinal plants within their immediate surroundings because these plants are overexploited and threatened with extinction. Overexploitation of medicinal plants is a serious threat to the availability of these plants and this is due to their intensive harvesting in relation to high demand (Street & Prinsloo, 2013).

The use of medicinal plants for the purposes of primary health care needs is still a prosperous industry across South Africa, despite the pressing challenges mentioned above (Magoro, 2008). The majority of South African rural communities still prefer the use of medicinal plants for the purposes of their primary health care, in spite of the availability and accessibility of western medical care services provided by the government (Williams *et al.* 2013). De Wet, Nciki & van

Vuuren (2013) also state that majority of the South African population have access to the western health care facilities. However, they still prefer to use medicinal plants as the primary health care for the treatment of various diseases. The majority of people who use traditional medicines prefer them because of their affordability, easy accessibility and cultural acceptability (Maroyi, 2013).

2.2.1 Notable scarce medicinal plants and scientific names

Literature on the research topic indicates that the 24 medicinal plants listed below are scarce across [Rural] South African communities (Refer to table 1).

Table 1: Common names of scarce medicinal plants, scientific names, parts used and ailments treated

| Referral terms in South African contexts | Scientific names | The parts used | Ailments treated |
|--|-------------------------|----------------|---|
| <i>Aloe vera, Mangane</i> | <i>Asphodelaceae</i> | Leaf | Wounds, Diarrhoea and cough |
| <i>N'tita</i> | <i>Annonaceae</i> | Roots | Helminthiasis |
| <i>Thlathlangati</i> | <i>Phyllanthaceae</i> | Roots | Helminthiasis |
| <i>Combretaceae Xicucutse, Xiwondzwana</i> | <i>Combretaceae</i> | Roots | Diarrhoea, dysentery, helminthiasis, UTI, wounds |
| <i>Tsenga</i> | <i>Fabaceae</i> | Fruits | Wounds |
| <i>Mpfungura</i> | <i>Bignoniaceae</i> | Fruits | Deep wounds |
| <i>Xihaca</i> | <i>Cactaceae</i> | Stem | Cough |
| <i>Xinkwakwani</i> | <i>Loganiaceae</i> | Roots | Helminthiasis |
| <i>Xibaha</i> | <i>Canellaceae</i> | Roots/bark | Mouth ulcers, cough |
| <i>Ximufane</i> | <i>Apocynaceae</i> | Roots | Diarrhoea |
| <i>Batata Africana</i> | <i>Hypoxidaceae</i> | Corm | Helminthiasis, diarrhoea, dysentery, wounds, Haemorrhoids |
| <i>Mavumbule</i> | <i>Aristolochiaceae</i> | Rhizome | Helminthiasis, internal wounds |
| <i>Xihlangwa</i> | <i>Celastraceae</i> | Roots | Diarrhoea, dysentery |
| <i>Nhathelo, Palhakufa</i> | <i>Asteraceae</i> | Roots | Helminthiasis |
| <i>Chiuane</i> | <i>Tiliaceae</i> | Roots | Cough |
| <i>Iridaceae Halahingwa</i> | <i>Iridaceae</i> | Bulb/roots | Diarrhoea, dysentery/ helminthiasis, Schistosomiasis |
| <i>Bimbe, Mahimbe</i> | <i>Clusiaceae</i> | Root and stem | Helminthiasis, diarrhoea, cough, dysentery |
| <i>Vela vahleka</i> | <i>Amaranthaceae</i> | Fruit | Furuncle |
| <i>Rompfha</i> | <i>Annonaceae</i> | Roots | Wounds and cough |
| <i>Mabope</i> | <i>Mapilghiaceae</i> | Roots | Diarrhoea, haemorrhoids |
| <i>Chinamane</i> | <i>Asteraceae</i> | Leaf | Wounds |
| <i>Phakama la hlanga/Phakama</i> | <i>Orchidaceae</i> | Stem, leaves | Cough, tuberculosis |
| <i>Xirrole</i> | <i>Rubiaceae</i> | Roots | Helminthiasis |
| <i>Bimbe, Mahimbe</i> | <i>Clusiaceae</i> | Roots and stem | Helminthiasis, diarrhoea, cough, dysentery |

Source: Barbosa *et al.* (2020).

It has been recorded that medicinal plants revealed by the THPs remain crucial concerning their practices (Magoro, 2008). It should be considered that medicinal plants need to be harvested in order to sustain the livelihoods of rural people, and to assist with development of strategies that effectively address the existing impacts of medicinal plants harvesting. Medicinal plants and their importance should be recognised and be understood better as a unique epistemology, which is united with individuality to the local THPs and numerous resources should be channelled towards preserving and protecting of medicinal plants (Magoro, 2008).

The plant species mentioned in table 1 remain important in curing various diseases, such as wounds, helminthiasis, tuberculosis, dysentery, kidney troubles and schistosomiasis diseases, to name a few. However, their harvesting through uprooting leads to their vulnerability, as they are not appropriately gathered in most occasions, making it almost impossible to grow back sufficiently. Practices that are notable often relate to continuous land-clearance, uprooting the entire plants, wood collection by cutting off branches, deforestation, drought and veld fires, owing to urbanisation and related developmental challenges pressures (Magoro, 2008). Magoro (2008) further shares that traditional medicine is grown on communal land. However, the current disparaging harvesting techniques, involving unprincipled intermediaries in the collection of these plants without creating any safety space for their protection and preservation remains a challenge.

As confirmed by the THPs, uprooting of plants should be regarded as part of the work for medicinal plants collectors (Magoro, 2008). However, THPs do not uproot the entire plants. Rather, they focus on the soil that is covering the roots, and they gently reveal their root structure and setup (Magoro, 2008). Equally, this technique of harvesting does not destroy the plant, but rather, ensures that the plant can regrow effortlessly since only side roots are removed, and the taproot is left undamaged (Magoro, 2008). In other instances, roots are harvested during flowering period and during rainy season since this ensures sustainability of these plants (Magoro, 2008).

3. RESEARCH DESIGN AND METHODOLOGY

With the application of exploratory research design, this qualitative study purposively selected 36 participants. The semi-structured interviews were employed for data collection. For data analysis, the 'Spiral data' analysis was adopted to organise data aligned to the objective of this study, while identifying relevant themes. The adopted research design was used to 'explore the effects of urbanisation on the availability of medicinal plants (Red data species) in the selected villages around Malamulele township of Limpopo province of South Africa, as listed in section 1 of this study (Maluleke, 2016; and Maluleke & Mofokeng, 2018). Neuman and Dwyer (2011) explain that this research design is used when the research subject is still very new and we have little or no information about it. According to Bless and Kathuria (1993), the procedure that a researcher chooses while trying to find a strategy to follow when they are conducting their research relates to the set of techniques that channel them during the process of verifying a hypothesis and excluding all other possible outcomes or details. It allowed the researcher to reach conclusions between the tested variables. On the other hand, Polit and Hungler (1985) state that research design refers to the researcher's overall plan for attaining answers to the provided research questions.

This study adopted a non-probability, purposive sampling. This sampling technique is often used in instances where a researcher conducts research with a particular purpose in mind and is most likely to produce the most valuable information (Denscombe, 2017). The selection process was based on targeted groups of individuals who may have information concerning the extinction of plant species. The proposed study was limited to the selected villages, which are deemed as Population Concentration Points in the CCLM Integrated Development Plan (2021/2022). Historically, these villages had an abundance of medicinal plants. However, the introduction of urbanisation in the area, started the eradication of biodiversity, which had a direct negative effect on medicinal plants. The sample consisted of 36 participants. They included: One (01) Mayor, 01 Municipal speaker, 01 Chief Whip, 01 Municipal Manager, Two (02) Communications officers,

Six (06) Ward Councillors, 06 Traditional Leaders, 01 Steering committee member, 06 Community/traditional leaders and 11 community members' The researcher selected this sample to gather rich experiences, knowledge, opinions, and views on this subject.

For the purpose of this study, data was collected using the semi-structure interviews in order to get first-hand information from the participants. This study adopted Spiral Data Analysis to identify themes and patterns within the collected empirical qualitative data (O'Reilly & Kiyimba, 2015). Additionally, the researcher organised the obtained data through breaking responding to the objective of this study, with the use of index cards and by breaking down the large bodies of texts into smaller units, such as phrases. The researchers read the collected data several times to make sense of the shared perspectives and wrote down notes on the data in question. Themes and sub-themes were identified to give the researchers general sense of patterns in the collected data. Data was then integrated and summarised for the potential readers.

To this end, Creswell (2014) mentions that data analysis in qualitative research consist of preparing and organising the collected data and then reducing it into study themes. Thus, the employed data analysis method is described by Creswell (2014), as an analysis process used by researchers to organise the data, which they had obtained through breaking down the study objective, with the use of index cards and by breaking it down to large bodies of texts into smaller units such as phrases and keywords. To this end, the researcher read the collected data several times to get a perspective and wrote down notes on the reviewed literature studies and empirical data. Themes and sub-themes were identified to give the researcher a general sense of patterns in the-said data. This data was then be integrated and summarised for potential readers.

4. STUDY RESULTS AND DISCUSSIONS

For this specific section of data presentation, analysis and interpretation, the following questions were asked during the in-depth semi-structured interviews. Notes were taken and a voice recorder was used to record the participants' responses. Moreover, the referencing method for the conducted interviews in this study comprised a numerical sequence, adhering to the following notation example: (5:1:2). The 1st digit (5) relates to the folder number in the recording device. The 2nd digit (1) refers to the interview number, while the 3rd digit (1) cover the sequence of the cited interview, based on the conducted in-depth semi-structured interviews, guided by the same Interview Schedule Guide, consisting of the following 6 questions. All the selected participants were asked the following questions and their verbatim expressions are shared herewith:

- What is the nature of urbanisation to extinct medicinal plants in your area?
- Which plants species were used for health purposes in the past?
- Which of these plant species are no longer available in your area due to urbanisation?
- Which of these plant species are still available, but scarce due to urbanisation?
- In which places are medicinal plants still available in your area, despite urbanisation?
- What could have been done in order to preserve the plants' species that have come to an extinct owing to urbanisation?

The findings reported below were largely echoed by all the selected participants, regardless of the study location. For instance, their remarks regarding effects that urbanisation has on the availability of medicinal plants were similar. The participants indicated their knowledge on the

importance of medicinal plants, but these medicinal plants are mostly destroyed due to urbanisation in the area. On clearly understanding the nature of urbanisation to the extinct medicinal plants in your area, in this respect, Four (04) of the selected participants had the following to highlight:

In Malamulele area we still prefers to use medicinal plants to meet our primary health care needs regardless of the western health care services [public clinics and hospitals] that the government provide us with, hence the loss of medicinal plants that is influence by urbanisation affects our wellbeing. (In-depth interview-03:07:07)

In instance medicinal plants are found in the wild and when there are developments that are happening, like school building, and expanding of the city, amongst others, the wild is the targeted area for such development and medicinal plant are destroyed without any conservation methods to protect them. (In-depth interview-1:13:13)

One of the notable cases is the building of new Malamulele high school. The school is built at an area where people around the area used to collect medicinal plants to cue different diseases. The medicinal plants that were found in that particular area are Aloe vera, Mangane, Tsenga and Xibaha. Therefore, due to the large land that is used to build, the school majority of these medicinal plants were destroyed and no conservation measures were implemented during the course of clearing the land (In-depth interview-03:07:07)

Expansion of cities due to urbanisation, affects preservation and protection of medicinal plants in our area because in most cases we not even given an opportunity to suggest that medicinal plants should be protected before the developments resume. Thus, the larger portion of medicinal plants population is destroyed and lost due to urbanisation. (In-depth interview-01.01.01)

On the use of different plants species for health purposes in the past, 02 of the selected participants shared the following:

Majority of the indigenous people who reside in Malamulele areas depended in the use of medicinal plants that were found in the wild for their primary health care needs. In the past before most of these developments were implemented, when I have a toothache or stomach ache, I would just go to the wild to get leaves of Aloe Vera without even struggling because they were everywhere. Public clinics and hospital were far from where we reside and we will struggle to get transport to access those facilities, therefore we will rely on medicinal plants to cue different diseases since they were easy to access. I, personally preferred the use of medicinal plants be because of its free cost as compared to health care facilities that I had to pay for transport in order to access them. (In-depth interview-5:1:1)

Medicinal plants are organic and have less aftereffects as compared to western medicine, this is why I prefer the use of medicinal plants. In most cases people who have knowledge about the use of medicinal plant are indigenous people or better-known old people, and in order for that knowledge to remain existing our life time it is passed from one generation to the other. Old people share this indigenous knowledge with the young people through teaching them how to harvest and use those plants. Most of this knowledge is not not documented is not something that you can learn through reading a book but it is taught

verbally, this is the reason I am scared that the knowledge that has been existing for years might go in vain since these plants are getting extinct in the wild and I cannot share the same knowledge to my children and we are ending up relying on western medicine. (In-depth interview-1:13:13)

On which of these plant species are no longer available in their respective villages due to urbanisation, 02 of the selected participants revealed the following:

Urbanisation is good for our economic development, but it is damaging to our natural resources like medicinal plants. There are many medicinal plants that have come to an extinct in our area and are no longer found in the wild. Plants like Bimbe, Mahimbe, Vela vahleka, Rompfha, Mabope, and Chinamane are no longer found in the wild in Malamulele areas, meaning that they have come to an extinct in those particular areas, resulting in us abandoning the indigenous knowledge that was passed to us by our parents since we cannot access medicinal plants easily. Because of these medicinal plants that are already extinct in our area we are facing difficulty in meeting our primary health care needs in a way that we are used to. Most of the plants that are extinct are the ones that were found in areas where developments such as building of schools and shopping centres are implemented and all the natural resources were destroyed in those areas. (In-depth interview-01:12:13)

The plants that have come to an extinct due to urbanisation was because when those people were clearing the land they were uprooting and burning these plants leading to their existence to be completely destroyed. (In-depth interview-01:01:01)

In an attempt to understand which of these plant species are still available in the selected villages, but scarce due to urbanisation; 02 participants indicated that:

Medicinal plants such as Aloe vera, Mangane, N'tita, Thlathlangati, Combretaceae, Xicucutse, Xiwondzwana, Tsenga and Mpfungura are still found in the wild, however they are very scarce unlike in the past. Some of these plants are still available because we are able to plant them at the back of our yards. I have planted Aloe vera at my yard, so it makes it easier for me to access them, even though most of it is destroyed in the wild. (In-depth interview-02:03:14)

Urbanisation has had a greater effect on the availability and existence of medicinal and for us to access them is more difficult and because although most of the plants are already extinct some of them are still available but are very scarce and now we have limited access to these plants, because the natural supply of these plants is very low as compared to the demand from the general public. (In-depth interview-01:04:14)

The researcher was also interested in determining villages in which medicinal plants were still available despite various urbanisation processes, and the responses were as follows:

Urbanisation destroyed the majority of medicinal plants population in our area, but plants that are found by the side of the river and those that can be uprooted to be planted in another area are still available. Hence, we are most like to find medicinal plants that grows by the side of the river and the ones that we have planted in our own yards. The reason plants that grows by the side of the river are less likely to be affected by urbanisation is because most of the development activities are not done in such areas and the ones that plant in our own

are still available is because most of them is the leaf part that is used so it gives a plants a chance to grow again. **(In-depth interview-01:03:55)**

When the participants were asked what they thought could have been done in order to preserve and protect medicinal plants species that became extinct owing to urbanisation, 01 of the selected participants stated the following reason:

*Here in Malamulele we do not have lot of conservation methods that are used for the preservation of medicinal plants. If as a community had come up with various ideas of medicinal plants preservation against the effects imposed by urbanisation. We could have uprooted the medicinal plants and plant the in protected areas for their continued survival. Our leaders could have offered land that will be used as conservation area for the medicinal plants that have already come to an extinct due to urbanisation and the ones that are still available but scarce. **(In-depth interview-02:13:13)***

5. THE IDENTIFICATION OF STUDY THEMES AND CHALLENGES

- **Expansion of urban areas:** In Section 4 of this study, the participants state that the survival of medicinal plants is extremely affected by the expansion of urban areas into large portions of land in which these plants are found, particularly if they are not protected or preserved for future medical use.
- **The uncontrolled development activities:** In Section 4 of this study the results indicates that medicinal plants are facing extinction because of the uncontrolled development activities such as building of schools, shopping centres and development of roads. These developments affect the ecosystem and the availability medicinal plants in their natural habitat.
- **Indigenous knowledge:** Participants in Section 4 of this study point out that indigenous knowledge in Malamulele still plays a vital role in sustainable existence of a significant proportion of the Malamulele population of medicinal plants and that the knowledge of the use of these medicinal plants is passed on from one generation to the other verbally.
- **The removal of vegetation:** As indicated in Section 4 of this study participants agree that removal of vegetation from its roots, which is uprooting the entire plant and burning of land during urbanisation processes lead to completely destroying medicinal plant existence.

6. STUDY CONCLUSIONS AND RECOMMENDATIONS

6.1 Study conclusions

The aim of this study was to explore the effects of urbanisation on the availability of medicinal plants (Red data species) at Malamulele area of Limpopo Province, South Africa. The findings of this study point to the fact that urbanisation through the development of new settlements, the building of school and shopping centres, as well as the construction of roads, poses a threat to the survival of medicinal plants in the area under study. This urbanisation takes place as people who reside in villages around Malamulele relocate to urban settlements. This study also indicates that when urbanisation takes place and without the implementation of any measures to preserve or conserve medicinal plants, it leads to their destruction. Although there are institutions such as the Community-Based Natural Resource Management (CBNRM) that are established with the aim of

protecting and preserving medicinal plants, they are unsuccessful in protecting some of these medicinal plants.

As stated by McKinney (2008) in section 2.1 of this study, studies on the effects of urbanisation on the existence of medicinal plants indicate that urbanisation can either grow or decline the richness of the plant species, depending on various variables, and because the decrease in the richness of the species, it leads to medicinal plants becoming ~~to an~~ extinct or being scarce; thus making it hard for the rural community members to access these plants for their health needs. Thus, the issue of medicinal plants becoming extinct is recognised as a main problem in Malamulele and nearby areas. Summarily, studies indicate that urbanisation destroys the ecology of plants and therefore poses a threat to the survival of medicinal plants, and to the livelihoods and health of communities who depend on them.

In Conclusion, the purpose of this study was to explore the effects of urbanisation on the availability of medicinal plants in Malamulele area and to suggest possible ways to preserve and protect them while considering the importance of urban developments in selected Malamulele rural areas. The issue of urbanisation has been considered to have great effects on the availability of medicinal plants in this study. Recommendations are provided in the following section for possible applications by relevant stakeholders in Malamulele and the surrounding villages.

6.2 Study recommendations

This study can be used as a tool to provide relevant stakeholders with necessary information on urbanisation and its impact on the availability of medicinal plants. Further research studies could be conducted relating to this study area to ensure triangulation as a method of reliability. For the purposes of good practices to ensure that urbanisation does not further affect the availability of medicinal plants and to ensure that conservation methods are implemented for medicinal plants preservation and protection, this study makes the recommends that appear in Table 2 herewith.

Table 2: Recommendations to improve study aim and the identified themes and challenges

| Identified study themes and challenges | Recommendations |
|--|--|
| Study aim | The effects of urbanisation on the availability of medicinal plants (Red data species) in the Malamulele area of Limpopo Province, South Africa |
| Expansion of urban areas | While this study acknowledges that it is impossible to stop expansion of urban, it recommends that all plants that have medical applications and are found in those areas of the urban expansion should be preserved and protected in a safe space, which will be accessible to local communities. |
| Uncontrolled development activities | It is recommended by this study that during the process of development activities, most people, particularly traditional healers who are in need of medicinal plants on regular basis should be consulted and be given a platform to suggest how these medicinal plants could be preserved for future use. |
| Indigenous knowledge | This study recommends that local people with indigenous knowledge should be encouraged to share their knowledge with researchers in order for it to be documented and accessible when needed. They should also be allowed to be part of the conservation team and to participate in the documentation of medicinal plants. |
| The removal of vegetation | It is recommended that during urbanisation in which medical plants are uprooted, people should not destroy them but replant them in another area where they can be protected. |

PERCEIVED BENEFIT FACTORS INFLUENCING GENERATION Y STUDENT ATHLETES' INTENTION TO USE PERFORMANCE MONITORING DEVICES

C. Synodinos

North-West University, Vanderbijlpark, South Africa

A. Hattingh

North-West University, Vanderbijlpark, South Africa

ABSTRACT

There is a proliferation of performance enhancing devices in the sports technology sector as athletes increasingly use advanced equipment to measure their physical performance. The increased use of technology and its impact on athletic success prompted several companies to enter the lucrative market to manufacture performance monitoring devices (PMDs). It is predicted that the global sports technology market will be worth US\$30 billion by 2024, representing a significant growth rate of 20.63 percent since 2018. South Africa's wearable performance and fitness market generated \$2.43 billion in 2020, growing by 4.7 percent annually. The most prominent market segment regarding PMD adoption is the 18 to 34 year-old demographic, known as the Generation Y cohort. In light of student athletes' affiliation with the Generation Y cohort and their increased interest in purchasing and using PMDs, key perceived benefit (PB) factors that influence their intention to use (ItU) these devices were identified. In this regard, the technology acceptance model (TAM) (Davis, 1989) and the model by Yang et al. (2016:258) were used as a theoretical foundation to explain the PB factors, including perceived usefulness (PU), perceived enjoyment (PE_n) and perceived ease of use (PE_oU), influencing South African student athletes' ItU PMDs. In this regard, 26 universities were considered, where a purposeful sample of student athletes who compete under the auspices of University Sport South Africa (USSA) and who belong to the Generation Y cohort, was selected. The quantitative data were collected and analysed through a self-administered online survey, which included 315 viable questionnaires. Various statistical analyses, including reliability and validity analysis, descriptive statistical analysis and regression analysis were performed on the collected data. The findings indicate that PU, PE_n and PE_oU significantly influence South African student athletes' ItU PMDs. As such, PMD manufacturers and marketing practitioners should promote these devices' usefulness, advanced features and aesthetic appearance to increase student athletes' usage intentions.

Keywords: Performance monitoring devices; Generation Y student athletes'; Intention to use; South Africa

1. INTRODUCTION

Performance monitoring devices (PMDs) consist of diverse tracking mechanisms, including heart-rate monitors, smart shoes (Johnson, 2019), sensor sports bras (Schultz, 2019), wristband cardio trackers (Gibbs, 2015), smart sleeves (Seshadri et al., 2019:71), remote-controlled cameras (Fleischhacker, 2019) and sensor arrays (Tekscan, 2019). These devices are either worn by athletes or placed around the sports field where athletes train and compete (Ohio University, 2020). In this

way, coaches and sports scientists can accurately analyse athletes' performance during training sessions and competitions (Lazzarotti et al., 2019; Sanyal, 2018). The sportswear and PMD industries have recorded unprecedented growth within the global (International Data Corporation, 2017) and South African market segments (Business Tech, 2018; Muller et al., 2018:85), where key industry players have introduced an increasing number of PMDs to take advantage of this promising market (Pfeiffer et al., 2020:2). To put this into perspective, the global wearable PMD market is estimated to grow at a significant rate of 17.6 percent from 2020 to 2024, reaching a value of US\$30 billion (Market Intelligence Data, 2022), while South Africa's performance and fitness market is predicted to grow at a sustained rate contributing to a market volume of R2.91 billion by 2024 (Research and Markets, 2021).

Individuals aged between 18 and 34 years are most interested in adopting PMDs (Statista, 2019) given the advent of innovative technology and devices, which motivates them to keep up to date with the latest trends in their sport community (Wellnessliving, 2019). Markert (2004:21) conceptualises this group as part of the Generation Y cohort. The Generation Y cohort consists of individuals born between 1986 and 2005, a segment that student athletes form part of. It is well-known that Generation Y has been significantly shaped by growing up in the era of digital connectivity (Bevan-Dye, 2016:4), and comprised approximately 34.1 percent of South Africa's total population in 2021 (World Population Review, 2021). In order to tap into this opportunistic market, it is critical to determine how to drive effective marketing campaigns towards the student-athlete market (Pillay, 2020).

Student-athletes refer to individuals who devote themselves to the advancement of their own personal and professional sporting careers (Condello et al., 2019). Utilising PMDs to obtain specific training and competition data is integral to student athletes' holistic preparation and for evaluating their performance during competitions (Thornton et al., 2019:698). Student-athletes are viewed as the future stars of South African sport and the use of PMDs is essential not only to their success, but also for marketers seeking to take advantage of this lucrative growing market segment (Sanyal, 2018). Therefore, this study aimed to focus specifically on the perceived benefit (PB) factors influencing Generation Y student athletes' ItU PMDs.

2. LITERATURE REVIEW

There is a tendency for consumers to accept PMDs quicker when the possibility to gain several benefits from the device exists (Kim et al., 2019:142). The benefits of PMDs motivate consumers to use these devices when it is effectively advertised (Aksoy et al., 2020:228). PMD marketing practitioners must therefore emphasise the benefits of these devices in a persuasive manner to positively influence consumers' usage intentions towards PMDs (Lunney et al., 2016:218). This is particularly necessary, since a number of South African student athletes are not using PMDs regularly due to a perceived lack of benefits (Halson, 2014:140).

For the purpose of this paper, two important theoretical models have been found applicable in explaining the importance of specific PB factors influencing student-athlete's usage intentions towards PMDs, namely the technology acceptance model (TAM) (Davis, 1989) and the model of Yang et al. (2016). According to the TAM, perceived usefulness (PU) and perceived ease of use (PEoU) are the most important drivers of a user's attitude and intention to use (ItU) technology (Davis, 1989). This is strengthened by prior research that found various significant relationships

between PU and ItU technological devices (Byun et al., 2018:58; Kim & Chiu, 2019:118; Park & Chen, 2007:1357; Pfeiffer et al., 2016:10), as well as between PEOU and ItU technological devices (Chinomona, 2013:266; Revels et al., 2010:74; Wong & Mo, 2019:36). PU within the context of PMDs can be described as the value or benefits users believe they can obtain when they use PMDs (Lunney et al., 2016:115). The usefulness of PMDs is often based on factors associated with increased productivity, improved performance outcome, as well as allowing student athletes to access information anywhere and anytime, which strengthens their intention to use these devices (Talukder, 2019:181). However, consumers tend to have negative perceptions towards technological devices when it requires more effort to use or when perceived risks are present (Chang et al., 2016:520). To counter this phenomenon, manufacturers and marketing practitioners should promote the overall usefulness of PMDs in such an appealing way that consumers' usage intentions towards PMDs increase (Chang et al., 2016:520). Moreover, PEOU can be described as the extent to which an individual believes that technology usage will be free from mental effort (Davis et al., 1989:320; Turhan, 2013:376). As Park et al. (2016:719) explain, technological devices perceived as easy to use are also considered useful in daily tasks. The idea that technological devices are more useful for consumers when they are simple to operate is widely held (Kim & Chiu, 2019:114; Venkatesh, 2000:343). Consumers have higher intentions to use technological devices when they are easy to learn, simple to manage, understandable and able to be adapted to users' different activities (Davis, 1989:322), which could result in enhanced sales of these devices (Lunney et al., 2016:118).

The second theoretical model applicable to this study (Yang et al., 2016:258) focusses on the ItU of PMDs. Fishbein and Ajzen (1975:216) define ItU as “a measure of strength concerning one’s intention to carry out a certain behaviour”. Building on this definition, consumers’ usage intention towards technology is influenced by the devices considered useful to their lifestyle in general (Lunney et al., 2016:115). Therefore, it is evident that consumers’ ItU technological devices are influenced by their behavioural habits, where purchasing intentions and decisions correlate with the PBs they obtain from their daily routine (Choi & Kim, 2016:780). Yang et al. 's. (2016:258) model proposes that consumers’ ItU is influenced by their perceived value, which, in turn, is influenced by their PB and perceived risk factors of technological devices. However, for the purposes of this study, the focus will be on the perceived enjoyment (PE_n) PB factor from Yang et al. 's (2016:258) model, which is used as part of the theoretical foundation for this research. In accordance, PE_n is described as the happiness, fun or pleasure that consumers experience when using a particular technology, apart from any expected performance consequences (Lee et al., 2005:1099; Venkatesh et al., 2012:161). This notion is supported by Park et al. (2012:382) who suggest that consumers are more likely to accept and use innovative technologies if they find the product enjoyable. It should also be noted that users of PMDs have higher levels of perceived enjoyment when advanced features and capabilities are integrated into devices that increase users' ItU PMDs. Therefore, PMD manufacturers need to develop specific features enhancing student athletes' perceived enjoyment of PMDs (Naglis & Bhatiasevi, 2019:101146). Moreover, PE_n is classified as an important factor that encourages consumers to adopt specific technology and is therefore a direct influencer of ItU (Dickinger et al., 2008:4). Various research studies shed light on the importance of PE_n as a PB as well as the significant relationships between PE_n and ItU PMDs (Ha et al., 2017:281; Naglis & Bhatiasevi, 2019:101146; Pfeiffer, 2016:10). It is therefore imperative that PMD manufacturers and marketing practitioners gain deeper insight into the PB

factors that may influence South African student athletes' ItU PMDs, as this information will provide deeper insight for PMD manufacturers and marketing practitioners to produce and advertise according to student athletes PBs.

3. METHODOLOGY

3.1 Research design

In this study, a descriptive research design was employed in order to investigate a purposeful sample of student athletes forming part of the Generation Y Cohort. The aim of this research design is to identify and select individuals or groups who have specific knowledge or experience regarding a particular topic (Cresswell & Clark, 2011:175).

3.2 Target population

The target population of the study comprised South African Generation Y student athletes aged between 18 and 34 years. The target population is described as follows:

- Element: Student athletes aged between 18 and 34 years.
- Sampling unit: Student athletes who competed under the auspices of University Sport South Africa (USSA participants).
- Extent: South Africa, hockey, rugby, netball, cricket and basketball university teams
- Period: 2020–2021

3.3 Sample size

The sample size of this study was 500 student athletes. Taking into consideration that the research relating to PMD is limited, the sample size of this study was based on previous research studies that consist of the adoption of new technology and activity-related wearables, such as Dwivedi et al. (2019) (sample size 459), Muller (2019) (sample size 480), as well as Ooi and Tan (2016) (sample size 459), which is, therefore, deemed sufficiently large.

3.4 Measuring instrument and data collection technique

In light of the COVID-19 lockdown and total sports event suspension during data collection, the researcher used online data collection by approaching USSA, sport managers and coaches at university clubs to post the questionnaire link on the sports team's WhatsApp group. Using this approach, student athletes were not directly contacted and were able to complete the online questionnaire voluntarily and anonymously. The measuring instrument comprised existing scales used in previous studies. According to Heggstad et al. (2019:2617) an adapted scale is merely the adaptation of the wording of scale items, without altering the context or antecedent. It is crucial to gather data in support of a scale's validity during the adaptation process (Korb, 2012). The questionnaire comprised three sections. The questionnaire entailed a section regarding the demographic information of student athletes and a section where student athletes were required to answer scaled questions based on previous publications. The adapted scale of Park and Chen (2007) was used to measure PU (six items), while the four-item PEOU scale was adapted from Kim and Chiu (2019). Student athletes' PEn towards PMDs (four items) was measured by adapting the scale of Sweeney and Soutar (2001) and Venkatesh (2000); whereas Hsu and Lin's (2015) scale were adapted to measure student athletes ItU PMDs (four items). Scaled responses were measured

on a four-point Likert-type scale, ranging from 1 = strongly disagree to 4 = strongly agree. The captured data were analysed using IBM SPSS Statistics 27 and Analysis of Moment Structures (AMOS), Version 27.0.

4. RESULTS AND DISCUSSION

The results for this study’s data set were computed using IBM SPSS Statistics 27. Numerous statistical techniques including outlier statistics, internal-consistency reliability, descriptive statistics, correlation analysis, regression analyses and an independent samples t-test were undertaken to reach the objectives set out for the study.

When working with smaller sample data sets it is highly advisable to screen the sample for case subjects who may be outliers, as these cases may skew data results (Pallant, 2013:127-128). These “outliers” are cases that appear outside of the general norm, either above or below the average response consensus (Hair, Black, Babin & Anderson, 2010:65; Pallant, 2013:127-128). As such, a Mahalanobis static analysis was undertaken on this data set in order to determine if any outliers were present in the sample. Owing to the study containing four variable constructs, the Mahalanobis statistic cut-off level was set at 18.467 (chi-square value for $\alpha=0.001$ at 4 df). As a result, any case achieving a statistic higher than the cut off level would then be liable for removal from the data set. The identifying case numbers were set as the dummy dependent variable and the measuring constructs were set as independent variables. Table 1 below displays the top 10 Mahalanobis distance statistics from the data set.

Table 1: Outlier statistics

| | Case number | Statistic |
|-----------------|--------------------|------------------|
| Mahal. Distance | 1 | 57 |
| | 2 | 314 |
| | 3 | 195 |
| | 4 | 67 |
| | 5 | 290 |
| | 6 | 107 |
| | 7 | 9 |
| | 8 | 252 |
| | 9 | 209 |
| | 10 | 13 |

Note: Bold cases were deleted

As can be seen in Table 1, only one of the Top 10 Mahalanobis statistics were greater than the cut-off level of 18.467 (chi-square value for $\alpha=0.001$ at 4 df). Subsequently, it was deemed that the removal of Case 57 from the data set would not warrant any concern and was then deleted. As such, the data set now contained 330 viable responses for statistical analysis.

4.1 Internal-consistency reliability

The internal-consistency reliability of the measuring constructs was assessed using the popular Cronbach’s alpha statistic. The statistical range for the Cronbach’s alpha is 0 to 1 where values below 0.50 indicate unacceptable internal-consistency reliability and values equal or greater than 0.70 are considered to be good to excellent reliability (Zikmund & Babin, 2013:257; Malhotra, 2010:319). Table 2 displays the Cronbach’s alpha values for the constructs used in this study.

Table 2: Reliability analysis

| | Items (n) | Cronbach's alpha |
|-----------------------|-----------|------------------|
| Perceived usefulness | 6 | 0.88 |
| Perceived ease of use | 4 | 0.90 |
| Perceived enjoyment | 4 | 0.91 |
| Intention to use | 4 | 0.85 |

The data sets internal-consistency analysis yielded Cronbach's alpha values above 0.80 for all measuring constructs. This is an indication that all constructs possess excellent reliability. The two highest recorded scores were that of perceived enjoyment and perceived ease of use (PEoU) obtaining values of 0.91 and 0.90, respectively. Therefore, the measuring instrument may be deemed as reliable for achieving the studies objectives.

4.2 Descriptive statistics

Descriptive statistics were computed to closely inspect the sample characteristics in terms of means, data shape and distribution. Additionally, a samples t-test was conducted to assert the significance of each of the constructs means. The measuring questionnaire used a 4-point Likert scale, resulting in an expected mean level of 2.50. The significance level was set at $\alpha = 0.05$ and the results are depicted in Table 3.

Table 3: Descriptive statistics

| | N | Means | SD | t-value | p-value | Skewness | Kurtosis |
|-----------------------|-----|-------|------|---------|---------|----------|----------|
| Perceived usefulness | 330 | 3.34 | 0.51 | 117.65 | 0.000 | -0.32 | -0.43 |
| Perceived ease of use | 330 | 3.28 | 0.52 | 113.68 | 0.000 | -0.02 | -0.60 |
| Perceived enjoyment | 330 | 3.29 | 0.57 | 104.65 | 0.000 | -0.29 | -0.52 |
| Intention to use | 330 | 3.35 | 0.48 | 124.70 | 0.000 | -0.09 | -0.79 |

p-value: two-tailed significance

Each measuring construct surpassed the expected mean threshold of 2.50 and each said mean was statistically significant at the $p \leq 0.05$ level, as can be seen in Table 3. The consensus of these results implies that Generation Y student athletes perceive PMDs as useful, easy to use devices and have great enjoyment when using them. Moreover, this generation displays a positive ItU these devices in the near future.

In terms of the data sets normality and distribution, the skewness values of each construct were between the recommended range of -2 and +2. Moreover, all kurtosis values fell between -7 and +7 indicating no cause for concern (Kalkbrenner, 2022; Berndt & Petzer, 2011).

4.3 Correlations analysis

A Pearson product-moment analysis was performed to see if any of the measuring constructs had underlying relationships among them. The Pearson value (r) ranged from 0 to 1 in which an $r \geq .50$ equates to a strong associating relationship, $r \geq .30$ indicates a good or moderate relationship and $r \geq .10$ denotes a weak relationship between construct variables (Pallant, 2016:150; Pallant, 2013:139). Table 4 below represents the correlation matrix of the data set.

Table 4: Correlation matrix

| Constructs | 1 | 2 | 3 | 4 |
|-----------------------|---------|---------|---------|---|
| Perceived usefulness | 1 | | | |
| Perceived ease of use | .355**M | 1 | | |
| Perceived enjoyment | .454**M | .431**M | 1 | |
| Intention to use | .639**S | .510**S | .582**S | 1 |

**Correlation is significant at the 0.01 level (2-tailed)
W = Weak relationship; M = Moderate relationship; S = Strong relationship

As can be seen in the correlation matrix table above, each measuring construct displayed a statistically significant positive relationship at the $p \leq 0.01$ level among each other. Regarding the strength of the relationships, ItU PMDs displayed strong relationships with each of the independent variable. ($r \geq .50$). The largest relationship was between PU and ItU ($r = 0.639, p = 0.000 < 0.01$) PMDs, while smallest relationship, yet still significant and of medium strength, was between perceived ease of usefulness and PEoU ($r = 0.355, p = 0.000 < 0.01$). These associations indicate that Generation Y student athletes perceive PMDs as enjoyable, useful, easy to use and intend to purchase or use these devices in the future.

Regarding the data sets nomological validity and multicollinearity, there were no reasons for concern. Each pair of latent factors achieved significant correlation values at the 0.01 level, indicating that the data set has nomological validity. In addition, none of the correlation coefficients surpassed the 0.90 level indicating that respondents identified each variable as the researcher intended and the data set displayed no signs of multicollinearity (Hair et al., 2010; Malhotra, 2010:321).

4.4 Regression analysis:

Regression analysis was conducted to determine if and how much predictability was present for the independent variables of PU, PEoU and perceived enjoyment of ItU PMDs for student athletes. The results are depicted in Table 5 below:

Table 5. Regression analysis

| Variable | Standardised Beta | Adjusted R ² | t-value | Significance level |
|---|-------------------|-------------------------|---------|--------------------|
| Dependent variable: Intention to use | | | | |
| Independent variables: | | | | |
| Perceived usefulness | 0.425 | | 10.091 | 0.000* |
| Perceived ease of use | 0.288 | | 6.594 | 0.000* |
| Perceived enjoyment | 0.235 | 0.555 | 5.647 | 0.000* |

*Significance at the 0.05 level (2-tailed)

The regression results indicate that Generation Y student athletes' intention to purchase PMDs are positively influenced by their PU ($\beta = 0.425, p = 0.000 < 0.05$), PEoU ($\beta = 0.288, p = 0.000 < 0.05$) and perceived enjoyment ($\beta = 0.166, p = 0.000 < 0.05$). The largest contributor was that of PU with a β value of 0.425, therefore student athletes find PMDs useful and as such this will influence their intent of obtaining a PMD. The independent variables collectively explained 56 percent of the variance in ItU a PMD. As a result, it may be inferred that the independent factors can predict Generation Y student athletes' ItU PMDs.

5. CONCLUSION

The sports industry has greatly been transformed from recent innovations in performance monitoring and wearable technologies. This new innovative monitoring technology has influenced

sporting success from novice sportsmen/women to professional sportsmen/women and taken the world by storm, increasing interest in wearable technologies. Furthermore, the South African market is no exception to this interest, especially with the tech-savvy and economically strong Generation Y youth. As such, organisations have invested largely in this market resulting in both remarkable growth and profit generation. PMDs can offer a distinctive advantage over competitors and allow coaches to analyse the performance of athletes during both training sessions and competitive formats. This information may prove to be vital as the sporting industry is a multibillion-dollar industry.

This study illustrates the increasing interest the South African Generation Y student athlete has towards adopting a PMD. These individuals perceive PMDs as useful to their sporting activities and consider them as easily usable items. Furthermore, these individuals enjoy using these devices and display a positive intent to purchase a PMD. Consequently, organisations must capitalise on this new interest over these devices. Organisations should emphasise the need for performance monitoring devices by emphasising the competitive benefits of monitoring performance. Organisations should target athletes at all levels, not just professionals, to maximise profits.

DEVELOPING A CONCEPTUAL MODEL FOR ADDRESSING THE COMMISSION OF RAPE DURING HOUSE ROBBERY

K. Lekgau

University of Limpopo, Polokwane, South Africa

J. Barkhuizen

University of Limpopo, Polokwane, South Africa

ABSTRACT

There is an urgent need to address rape committed during a house robbery, as potential victims are subjected to unbearable victimisations, involving economic and sexual violations from perpetrator's ill actions. As a result, this paper offers a conceptual model to address the commission of rape during house robbery. This paper adopted a qualitative research approach, guided by the Grounded Theory research design. Twenty-three participants, namely: 15 offenders; 5 social workers; and 3 clinical psychologists, were selected using purposive sampling technique. A standardised semi-structured schedule of interview questions was implemented for the interviews. The collected data was analysed using the MAXQDA qualitative data analysis software. Moreover, with Grounded Theory methods of data analysis, aided by the MAXQDA software, open-, axial- and selective coding were applied to the data collected. A conceptual model, informed and guided by the motivational factors of committing rape during a house robbery, was developed. These factors included the following: unstable family background; aggression; dominance; opportunity; substance use; vulnerability; and mob mentality. This study concludes and recommends that the following selected factors: positive socialisation; sexual violence curriculum; liquor regulations; stringent firearms control; and target hardening, can best be used to respond effectively to the commission of rape during a house robbery. It is shared that an understanding of these factors can lead to the attainment of healthy morals and ethics in children from a young age. Furthermore, assist in reducing and/or eliminate the existing criminogenic factors that lead to sexual offending, as well as equipping and informing individuals about the nature and consequences of rape and house robberies.

Keywords: Conceptual model; house robbery; rape

1. INTRODUCTION

House robbery and rape are two distinct crimes. However, a direct link of violence and sexual victimisation exists between these crimes. Harris, Pedneault and Knight (2012) have highlight that if the assumed lack of financial and sexual motivation during house robbery and rape is removed, the committed crimes become one of power, invasion, control, or thrill. The number of common possibilities has resulted in a dearth of literature studies on the linked co-occurrences of these crimes. Accordingly, rape perpetrated in the context of house robbery is often viewed as an opportunity crime and qualifies as a 'bonus' to theft in commission (Warr 1988; Pedneault et al 2015).

As a result, a notable example of house robbery leading to rape being regarded as a 'bonus', occurs when a robber breaks and enters into a residence to commit theft and rapes a victim afterwards.

This often occurs when an offender, during a house robbery, encounters a powerless victim without guardianship to deter the criminal victimisation and chooses to rape the unprotected victims. This explanation is in accordance with the so-called ‘opportunistic rapist’ (Scully & Marolla 2014). It is against this background that there is an urgent and serious need to develop a conceptual model to address the commission of rape in a house robbery.

2. LITERATURE REVIEW

The conceptualisation of house robbery and rape

House robbery

House robbery is the term formulated by the South African Police Services (SAPS) to describe a robbery where the perpetrators overpower, detain, and rob the residents (occupants) of a residential premise (Zinn 2010; Zinn 2017). The author(s) assert that house robbery is the unlawful entering into a household with the intention to commit robbery while the occupants of the house are present. A house robbery involves careful planning of the routine activities of the victims, since it is only committed in their presence. The perpetrators can be profiled as individuals motivated by financial gain, since, in many instances of house robbery, wealthy households are the primary target. From this understanding, it can be deduced that house robbery is a planned and calculative criminal act wherein the perpetrators learn the routine activities of the victims and, upon entry into the household, there is the use of force that can result in the commission of other crimes, such as rape – as discussed in this paper.

Moreover, house robbery can occur with aggravating circumstances if weapons, such as knives or firearms, are used to scare the victims into submission and eliminate any actions of retaliation or response by the victims. In most incidences, access to the premises can be in two forms, either by force or the victims could unknowingly allow the perpetrators into the house (Alwinco 2015). The households that are mostly targeted are those that are wealthy and will make the crime rewarding (Van Raalte 2013; Chowles 2016). Zinn (2010) mentions that the information about the households is obtained from observation or the people currently working or who once worked on the premises such as domestic workers, gardeners, or security guards.

Newham (2008) further maintains that the perpetrators of house robberies are part of the criminal syndicates who quickly distribute the stolen goods, package them as second-hand goods and launder the money obtained from the stolen items. This is supported by Van Raalte (2013), who states that stolen items consist mainly of cash, jewellery and electronics. It would, therefore, appear that economic gain is one of the primary contributing factors in house robberies, since the perpetrators participate in these robberies to obtain quick cash. This analysis can be attributed to the Strain Theory, which states that people commit crimes because of the limited legitimate resources accessible to them within societies (Van der Westhuizen 2011).

Furthermore, they gain experience in stealing goods by committing petty/street crimes before criminal career progression to house robbery. Normally, robbers commit a substantial number of crimes before they are apprehended for a house robbery (Zinn 2010). Accordingly, in this regard, as proposed by the Broken Windows Theory of Wilson and Kelling (1982), the perpetrators of petty crimes must be arrested, prosecuted and convicted to deter their progression into more serious

criminal activities. Consequently, for the successful completion of the crime, the victims are usually subjected to different kinds of violence ranging from: torture; assault; physical abuse; to rape and murder (Zinn 2010).

***Modus Operandi* of burglars at residential premises**

Nee (2010), in his study of convicted burglars, emphasised three main factors concerning a burglary at residential premises. The first aspect is the decision made to commit a crime that follows a certain pattern. The first decision happens away from the scene, based on a certain motivation, which may, for example, be a need for money. This is followed by searching for an area that is vulnerable until they find a suitable target, namely, in this instance, a suitable residential property.

The second aspect is their interest in the cues that alert them about how accessible is the property, the occupancy, i.e., who lives there, surveil ability and security installed at the target residence. The last aspect refers to how the burglar carefully considers a specific *modus operandi* to gain entry to target residence. De Wet, Potgieter and Labuschagne (2010) highlight the variables that indicate the vulnerability of a potential victim to the perpetrator. These include victim being a woman; the victim's age range; being reliant on public transport in general and the need to get employment. Accordingly, the conceptualisation of rape is as follows:

Rape

According to Section 3(1) of The Criminal Law (Sexual Offences and Related Matters) Amendment Act, No. 32 of 2007 (SOAA):

“Any person (“A”) who unlawfully and intentionally commits an act of sexual penetration with a complainant (“B”), without the consent of B, is guilty of the offence of rape. It further refers to incidences wherein the offender penetrates the vagina or anus of the victim with a body part other than the penis or an object manipulated by the offender.”

It is noted that the 2007 Act was amended in 2021 and the new act was signed into law on 28 January 2022 as The Criminal Law (Sexual Offences and Related Matters) Amendment Act Amendment Act, No. 13 of 2021. Additionally, Section 261 of the Criminal Procedure Act (CPA) No. 51 of 1977 stipulates the elements that must be proven beyond a reasonable doubt in rape cases such as unlawfulness, intent, no consent, and penetration. Toates (2014) further suggests that sexual assault is the result of a motivational mechanism in which dominance/aggression and sensation seeking can interfere with sexual desire. The stance taken by Toates (2014) is endorsed by Fiske and Rai (2014), namely that: superiority and the assertion of authority are usually part of the motivational basis for rape. Darke (1990); Jewkes, Sikweyiya, Morrell and Dunkle (2010); and Mann and Hollin (2010), take much stronger stances and declare that the reason for rape seems to play a role in the urge to dominate and humiliate. This view was reinforced by Hazelwood and Burgess's (1987) Federal Bureau of Investigations (FBI) typology, based on the work of Groth and Birnbaum (1978), which states that power-reassurance offenders commit rape in an attempt to challenge their sexual doubts and perceived inadequacies.

Furthermore, a study conducted by Holmes and Holmes (2009) highlights that most male sex offenders were sexually, physically, and verbally abused as children and this is an instrumental

factor in their hostility towards women. Additionally, Zinn (2017) states that the use of alcohol and drugs plays a vital role in the commission of the crime of house robbery. That is, alcohol eliminates moral constraints and consequently, vulnerable victims are attacked during a house robbery when the desire for sex becomes unbearable and irresistible. A study, conducted by Bruce, (2007) concurs with the views of Zinn (2017), and highlighted that alcohol and drugs emerged as the most significant disinhibiting factors amongst the majority of interviewees undertaken with sexual crime offenders, and specifically in the instances of rape.

Therefore, rape in the context of this paper, can be defined as a sexual penetration with a female without her consent influenced by power, dominance, opportunity and the victim's vulnerability. Rape committed in the context of house robbery can be attributed to the victim as a powerless woman with the act enabled or facilitated by the opportunity provided, given that it was not the perpetrator's initial motive to commit a rape during the commission of the house robbery. From the above, it can be deduced that the perpetrators of house robbery and the occurrence of the subsequent rape are categorised as: 'opportunistic dominance rapists'.

2.1 Theoretical framework

Power Control Theory

The Power Control Theory explains that gender differences in delinquency are based on the power structures displayed within a family unit and the differential parental controls exercised over boys versus girls. According to Lilly, Cullen and Ball (2011), the balance of power and control between parents affects the child's preference for taking risks and delinquency. The key issues in the Power Control Theory are the differences in the mother's and father's occupational authority (egalitarian and patriarchal respectively). In a patriarchal family, the father's job puts him in a 'command' role, while the mother is obliged to follow an 'obey' role. Thus, the children in patriarchal families are socialised by their parents to reproduce gender relations (Lilly, Cullen & Ball 2011). This means that daughters are taught to be feminine and prepared to be homemakers, while on the other hand, sons are taught to be breadwinners and are allowed to experience the world.

Therefore, the occurrence of rape in the context of this paper results from the poor socialisation and parents' lesser control over the male versus female children in the family. Additionally, males exposed to poor socialisation in these households can be prone to criminality when confronted with a powerless victim. Rape in this context is not just about sex, but about domination, social control and violent acts directed at women – all perpetuated by poor socialisation. In essence, women are viewed as belonging to the 'obey' position, while men are seen as 'commanders.' Women are obliged and forced to obey anything that a man commands without their consent. Sexually violent acts are no exception to this dictum.

3. RESEARCH METHODOLOGY

3.1 Research design

A Grounded Theory research design was employed in this study, since it is embedded in behaviours and social movements. The use of this research design was to open up a space for the development of a new, contextualised theory. Glaser and Strauss (1967) define Grounded Theory

as the discovery of theory from data systematically obtained from social research. Additionally, according to Creswell (2009), Grounded Theory research design is "...a qualitative strategy of inquiry in which the researcher derives a general, abstract theory of process, action, or interaction grounded in the views of participants in a study". The author(s) endeavoured to use the 'voices' of participants to develop a theory on house robberies that result in rape through the use of Grounded Theory.

3.2 Sampling method

Purposive sampling was applied in this paper to guide data collection and generation of data. The participants were purposefully chosen to answer the research questions (Chun Tie, Birks, & Francis, 2019). The target population sample comprised of incarcerated offenders of house robbery and subsequent rape from correctional facilities in the Gauteng and Limpopo provinces of South Africa. The sample included a select few social workers and clinical psychologists. The target population sample consisted of 23 participants, namely: 15 offenders; 5 social workers; and 3 clinical psychologists.

3.3 Research instrument

The semi-structured face-to-face interviews with reference to the 'Interview Schedule Guide' channelled this process to define the topic under research and provide opportunities for both interviewer and interviewee to discuss some topics in detail. Semi-structured interviews allow the researcher to prompt or encourage the interviewee to provide additional information. According to Barclay (2018), this offers the freedom to "probe the interviewee to elaborate or to follow a new line of inquiry introduced by what the interviewee is saying" and this blended in well with the requirements of the Grounded Theory methodology. The interview process was first implemented at the Thohoyandou Correctional Centre in the Limpopo Province, and then moved on to the Kgosi Mampuru II Correctional Centre in Pretoria in the Gauteng Province,. Moreover, the offenders were housed at Medium B and C Max Maximum security) sections at both Thohoyandou and Kgosi Mampuru II correctional centres.

3.4 Data collection

Data collection through Grounded Theory is directed by purposive sampling. Its advantage is that it enables the selection of subjects that maximise the potential to discover as many dimensions related to the phenomenon as possible. Qualitative one-on-one interviews are best suited for understanding people's perceptions, experiences and for gaining in-depth knowledge on the interview topic directly from interviewees (Blandford 2013). In addition, the interviewees can discuss their perceptions and interpretations regarding a given situation. Therefore, semi-structured interviews were used to allow participants the freedom to express their views (Crabtree & Cohen 2006).

3.5 Data analysis

(Chun Tie, Birks, & Francis, 2019) provides that concurrent data generation, collection, and analysis is essential in grounded theory research design. Therefore, before proceeding with further data collection/generation, the researcher collects, codes, and analyses the initial data.

Additionally, purposeful sampling provides the researcher with the initial data for analysis. Theoretical sampling then begins, with the codes and categories developed from the first data set. As the study progresses, theoretical sampling is used to identify and follow clues from the analysis, fill gaps and clarify uncertainties (Chun Tie, Birks, & Francis, 2019). Theoretical sampling is described as the process of continually gathering data through the analysis process to explain and validate emerging concepts (Charmaz 2014). It is further defined as the process of collecting, coding and simultaneously analysing data to subsequently formulate a theory (Glaser & Strauss 2012). This process commonly entails soliciting specific participants that will provide further facts on the specific concept under investigation. An advantage of the application of theoretical sampling is that it provides a structure of data collection and analysis processes.

The collected data was analysed using the Grounded Theory, through the MAXQDA qualitative data analysis software, which utilises a process of breaking down, organising and reassembling data to develop a different understanding of phenomena (Strauss & Corbin, 1998). The first phase of data, which was collected from the Thohoyandou Correctional Centre, was analysed using open coding of concepts and categories. The categories/themes generated from the data were used as a framework to modify the interview schedule for the second phase of data collection, which was implemented at the Kgosi Mampuru II Correctional Centre. The process was facilitated by a constant comparative method, which is deemed an original way of organising and analysing qualitative data in Grounded Theory (Chun Tie, Birks & Francis 2019). Data analysis continued until there were no new emerging categories or themes. It was at this stage when a theory was developed. The themes that emerged were, namely: opportunity (to commit a rape presented during a house robbery); unstable family background; substance use; aggression; (need to establish) dominance; (victim) vulnerability; and mob (gang) mentality.

4. RESULTS AND DISCUSSION

The analysis raised five concepts connected to rape committed during a house robbery. These include: i) Positive socialisation; ii) sexual violence curriculum at schools (life orientation) from the primary level; liquor regulation; enforcement of stringent firearm control and target hardening. The house robbery and subsequent rape conceptual model is highlighted and explained as follows:

Figure 1: Conceptual model to address the commission of rape during a house robbery

Positive socialisation

In the majority of African and Western households, norms and values are clearly and verbally learned through ‘word of mouth’ within a family environment. Therefore, positive socialisation of the offsprings plays an enormous role in shaping future law-abiding citizens. A family is the first and primary unit of socialisation that plays a positive role for individuals. As a result, parents play positive roles in shaping existing behavioural patterns of their offspring. This can be done through their own exhibiting and teaching their children positive norms and values, to avoid the latter falling prey to delinquent behaviour.

Moreover, a sexual violence culture can be mitigated by abolishing dominant patriarchal ideologies that perpetuate male superiority. In addition, working on social and cultural inferiority that undervalues women, is crucial in this context. Furthermore, families should account for and refrain from any abuse that may hamper the socialisation of a child. Sexual, physical, emotional, and psychological abuse during childhood has been proved to contribute, later in life, to an offending behaviour. Additionally, during the perpetration of rape in a house robbery, the consequential factors of these patriarchal ideologies are domination, accompanied by aggression. Therefore, the imparting, from a very tender age, of positive socialisation to offspring can serve as a proactive factor to curb the occurrence of rape during a house robbery.

Sexual violence curriculum

Knowledge will always be a powerful weapon that can be used to fight any crime and social ills. Knowledge about sexual violence imbued within the schooling environment, can assist individuals to develop conscience whenever confronted with the opportunistic circumstances for the commission of rape during a house robbery. The schooling environment reinforces all the ideas and norms about sex, relationships, and bodily autonomy. There is a need for the incorporation of the sexual violence curriculum within primary and secondary schools, as well as tertiary institutions. Children need to be familiar with the details and literature of sexual violence and popularise the application of ‘consent’.

Additionally, for rape to occur a certain element needs to be proven beyond reasonable doubt, such as: lack of consent and therefore there is a need to educate children on what ‘consent’ entails with regard to rape. Schools are in a great position to carry out the difficult, grassroots task of educating children about the nuances and various aspects of sexual violence. Overall, it is imperative to incorporate sexual violence curriculum right from the primary school level, with a primary focus on sexual violence and related consequences. This curriculum could then also be enhanced by providing monthly/weekly views on identified emerging trends on the crime of rape. This can assist in the creation of further insight into this crime scourge and help in the development of best practices in dealing with it.

Liquor regulations

The majority of the participants in the study revealed that they were under the influence of alcohol during the commission of a house robbery and the subsequent rape. This factor, also highlighted the provision in the liquor licensing conditions that refers to the serving of alcohol to already intoxicated patrons, which is a punishable offence. The stricter regulation of liquor is of utmost importance given the negative consequential nature associated with binge drinking. Therefore, there is a dire need for liquor license holders to comply with all the conditions as set out in the legislation and regulations that impose controls on the sale and provision of alcohol, in particular to underage youth. The use of breathalysers (alcohol testers) at liquor outlets should be a mandatory condition imposed on license holders by the Liquor Board. The use of breathalysers would enable liquor license holders to check individuals that are already intoxicated and restrict the sale of alcohol to them. This can be a proactive measure to avoid circumstances wherein individuals become intoxicated and proceed to commit house robbery and subsequent rape. Moreover, the use of alcohol has proven to facilitate the commission of these crimes and the

excessive use of it by the perpetrators can have detrimental effects on the victims of house robbery and subsequent rape.

Enforcement of stringent firearms control

The weapons such as firearms play a key role in the commission of house robbery and subsequent rape, since they are used as a threat of violence to scare and intimidate the victims into submission and to control the proceedings of the crime. Although South African history on firearms cannot be disputed, wherein the firearms that were used during the apartheid era are not all destroyed and confiscated. There were many legally licensed firearms from the apartheid era that were actually stolen post 1994 and circulated by criminals, for instance, readily available at the right price. Moreover, the problem is the implementation and incompetence of the Firearms Register Centres of the SAPS for its failure to curb firearms theft and implement proper control over licensed firearms. Added to this is the fact that the Central Firearms Register has been in absolute disarray with licence renewals not being done, compounded by incompetence and corruption in the issuance of licences. In addition, certain corrupt policemen have actually been apprehended for selling firearms to criminals. This calls for greater and stricter implementation of the existing firearms control regulations.

In terms of issuing of firearms to security companies, Minnaar, (2008) mentions that a security company in need of accreditation to use firearms for 'business purposes' should submit detailed information of the scope of the security service(business); secondly, a full motivation for the use of firearms in this scope of business. Thirdly, a detailed description of the exact firearms (with serial numbers) to be used as well as a detailed motivation of how those particular firearms would be used. Fourthly, it is imperative to provide a description of the security measures to be implemented in terms of safe handling, transportation and storage of the firearms. Fifthly, the total number of persons who would be issued with firearms to be used in the business to be licensed before issuing; and finally, a description of the premises from where the (security) business would be conducted. All these requirements are mandatory and therefore can play a crucial role in issuing accreditation of firearm use to the compliant security companies and control thereof.

Therefore, it is imperative that the Firearm Control act no (60 of 2000) be properly enforced, and the central firearm registers (CFR) be cleaned up and for it to start working properly and that stolen firearms must be reported. Additionally, the Firearms Control Act imposes on every registered firearms dealer to only sell ammunition to a licensed firearm owner on the presentation of the owner's firearm licence or the dealer accessing the Central Firearms Register database on the presentation of the firearm owner's identification(ID). In circumstances wherein there is a serial number, a firearm can be traced if the expended bullet and cartridge case are retrieved by the police and the bullet tested for striations (from the 'rifling' inside the barrel), as well as the firearm pin mark on the back of the cartridge case. All of this also presupposes the police have the actual firearm that fired the bullet and firing tests have been recorded by the firearm dealer that sold then legal weapon to an owner.

Target hardening

Crime prevention and control is a complex phenomenon and can only be maintained if there is a partnership between law enforcement agencies and community members. Communities' role in

crime prevention can be in terms of an active community Police Forum (CPF), community organised patrols, and other neighbourhood watch activities. Partial reference can be made to traditional policing to understand how target hardening can be maintained. Target hardening relates to control and security to limit, deter and restrict potential criminals from committing crimes and reduce possible opportunistic circumstances. Preferred neighbourhood wide CCTV managed by the Private Security Companies (PSCo) which can be paid by the community, alarm systems, electric fences, and domestic animals such as dogs can be used to alert and warn home dwellers of the early detection of an intruder on their property. The alarm systems within a household should be designed to detect the perpetrators whilst trying to bypass or penetrate the outside gate/wall (perimeter of property). The placement of alarm beams in a garden are another means of an alarm system providing early warning of any intrusion onto the property even before they enter the house itself. In essence, the vulnerability of a victim is exacerbated by easier entry of the perpetrator into the targeted house by the absence of any of the abovementioned security measures. Moreover, the wealthy households are prey to the perpetrators of house robbery and rape. Additionally, the same applies to the marginalised and low-security households.

Overall, a house alarm system should have the latest technological advancements installed, such as a cell phone application that is connected to the alarm system wherein a signal is sent to the home dwellers whenever there is an intruder on the property or any tampering of the security systems. Since the alarm system is linked to a private security company, the alarm is simultaneously sent through cellphone signal both to homeowner's and to the PSC's control room. Consequently, after receiving the alarm signal, the PSCo can immediately send an armed response team to the affected residential premises.

Additionally, visible policing can be a proactive measure to supplement the security features wherein the members of the SAPS and private security companies make regular patrols at identified crime hotspots in high-crime neighbourhoods, i.e. areas marginalised by being unable to afford private security company services. In this manner, the planning and studying of the routine activities of the home dwellers and free movement around neighbourhoods by criminals (house robbers in particular) in search of opportunities to commit a crime would be dramatically minimised and reduced.

5. CONCLUSION

This study analysed the conceptual model that was developed to understand the occurrence of rape during a house robbery. Furthermore, provided a detailed explanation of how these crimes can be more effectively addressed. This was accomplished through an explanation of the key categories of the model, namely: Positive socialisation; implementation of a sexual violence curriculum in schools and tertiary institutions; enforcement of liquor regulations; the stringent enforcement of firearm control and all the requirements stipulated in the Firearms Control Act; and target hardening of residential premises.

Therefore, an understanding of these points can lead to the achievement of healthy morals and ethics of children from a young age; the elimination of the criminogenic factors that lead to sexual offending; well-equipped and informed individuals about the nature and consequences of sexual violence and offending. Liquor license holders who comply with the conditions of the licenses of not selling alcohol to already intoxicated individuals. The control of firearms; and more stringent

security measures at homes coupled with additional visible policing patrols in high-risk areas for the prevention and/or reduction of the opportunistic circumstances for the commission of house robbery and subsequent rape.

THE ACCESSIBILITY OF SOCIAL FACILITIES BY RURAL AREAS IN SOUTH AFRICA: IS IT A MYTH OR A REALITY?

P.T. Mnisi

University of Limpopo, Polokwane, South Afrika

ABSTRACT

There has been a continuous debate on whether residents in rural areas of South Africa have access to social facilities such as education facilities, health facilities, community centres, sports centres, parks and other social facilities. The debate arises in lieu of Section 29 of the South African constitution which gives every individual a right to education. The state is responsible to ensure that everyone, be it in rural or urban areas, has access to social facilities. This paper is a theoretical intervention and relies on a literature-based methodology to investigate whether access to social facilities by rural areas in South Africa is a myth or a reality. A review of documents including newspapers, scholarly journal articles and government documents in relation to the accessibility of social facilities by rural areas in South Africa was conducted. Seemingly, access to social facilities by South Africa's rural areas is a myth, and not a reality. Numerous rural areas remain without access to social facilities. Consequently, people are forced to travel or walk many kilometres to access health, education and other facilities. The paper concludes that, decisions made regarding the accessibility of social facilities by rural areas in South Africa are merely a declaration without implementation. Hence, the paper recommends that the government of South Africa together with its stakeholders should examine the policies that were introduced to ensure that the constitutional mandate is fulfilled and realised.

Keywords: Social facilities; poverty; development; rural areas; South Africa

1. INTRODUCTION

There has been continuous debate on whether residents in rural areas of South Africa have easy and convenient access to social facilities such as education, health, community centres, sports centres, parks, among others (Mahaj, 2019). Section 29 of the South African Constitution gives every individual a right to education (Mahaj, 2019). One of the key principles supposedly undergirding the government of South Africa is to ensure that access to social facilities by all the citizens is improved and made easily available (White, Blaauw and Rispel, 2020). The provision of physical infrastructure for easy access to social facilities by communities is critical (Sulemana and Dinye, 2014). The infrastructure should be distributed spatially in such a way that it is logically centred on communities where they can easily access social facilities (Chisholm, 2012). The government is gravitating towards establishing more social services through the internet and other electronics (Mahaj, 2019). However, most social services require physical infrastructure, more especially rural areas (White, Blaauw, *et al.*, 2020). Eminent living environments are confidentially well provisioned and gain access within a workable gap to all the government amenities required to be in control of a treasured life (Chisholm, 2012). The society needs schools, health services, police stations, recreational spaces, etc., in their communities (Sulemana and Dinye, 2014). They also require access to social facilities such as the office of the Department of

Home Affairs and South African Social Security Agency (SASSA) as well as municipal services to manage their lives (Mahaj, 2019). However, for rural areas that are dispersed over the land, it becomes difficult for most services to be viably provided at all locations (Sulemana and Dinye, 2014). That there are difficulties should not be taken to imply that rural areas' access to significant services is not compulsory.

Existing development forms depict an unsatisfactory progress in the delivery of facilities (Chisholm, 2012). The design sometimes follows past settlement forms or income disparities; other forms demonstrate little levelheadedness, whereas others evince previous and current radical doctrines and/or political models that protract prejudiced social facility delivery (Sulemana and Dinye, 2014; White, Blaauw, *et al.*, 2020). Numerous guidelines, containing the Constitution and Public Services Regulations, place the responsibility on departments to advance access to services, to improve access ethics for their services and eradicate blockades that impact on access (Mahaj, 2019). The state must ensure that everyone, be it in rural or urban areas, has access to social facilities (White, Blaauw, *et al.*, 2020). However, there is still a huge number of rural areas without essential social facilities (White, Blaauw, *et al.*, 2020). Consequently, people are forced to travel or walk many kilometres to access health, education and other facilities (Chisholm, 2012). The people's rights to voice out the development they need is encouraged and even documented in South Africa; however, no action is ever taken to meet the need. This is why South Africa is still far from reaching the goal of poverty alleviation, equity and full employment. The purpose of this paper is to investigate whether the rural areas' access to social facilities is a myth or reality. It also seeks to examine the policies and other legal interventions that were introduced to ensure that the constitutional mandate that guarantees "the right to access social services or facilities" in South Africa is realised.

The paper comprises five sections. The first section introduces the paper. The second section is the literature review, which contains four sub-sections, namely: The theoretical framework; The legacy of apartheid; Rural areas and access to social facilities; The Constitution's obligations. The third section provides the methodology used while the fourth section provides the outline and discussion of the results of the investigation. The last section concludes the paper.

2. LITERATURE REVIEW

This section discusses the theoretical framework, the legacy of Apartheid on social facilities, Rural areas and access to social facilities, and the Constitution's obligations as follows:

2.1. Theoretical Framework

There has been a continuous debate on whether residents in rural areas of South Africa easy access to social facilities have to sustain their well-being (White, Blaauw, *et al.*, 2020). In view of this, this paper adopted the Social Welfare Theory because it purports the need to ensure the well-being of all societies (Mazibuko and Taback, n.d). The paper ascribes the responsibility of social welfare and well-being of all communities in South Africa to the government of South Africa. The theory further proffers that the dignity and eccentricity of a society should be valued through the delivery of social capitals (Mazibuko and Taback, n.d). During the provision of social facilities, the government and other stakeholders providing the social facilities are responsible to ensure that residents in rural areas are valued, respected and appreciated.

2.2. The lingering effects of Apartheid on social facilities

From a social welfare perspective, societies often have different levels of access to social facilities (Mahaj, 2019). In apartheid South Africa, even though white individuals were in the minority, they were still accorded better social well-being facilities than other ethnic groups (Gibson, 2003). Apartheid laws, policies and protocols (e.g. Populations Registration Act of 1950; the Pensions Circular 66 of 1966 and the National Welfare Act No. 100 of 1978), guaranteed that white individuals in South Africa would grow and protect economic resources (buy land and own the means of production) leaving other non-white peoples with minimal to no opportunities of access to economic development and prosperity (Gibson, 2003; cf. Chisholm, 2012; White, Blaauw, *et al.*, 2020). The gap between the rich and the poor in the country continues to widen in South Africa (Mahaj, 2019).

One of the greatest and substantial apartheid laws which categorised, endorsed distinct growth and engrained apartheid ideology is arguably the Populations Registration Act 1950 (Mahaj, 2019). This Act lucidly defined ethnic exceptionalism and exclusion among South African citizens, racially categorising them as White, Coloured, Indian and Black. However, in this categorisation, white citizens, acknowledged as genuine South African residents, were accorded voting rights while the other ethnic groups were marginalised and correspondingly taxed and denied freedom of the country as well as the privileges conferred upon white people (Mahaj, 2019). To this end, social welfare services were discriminately distinguished through monthly pensions in 1987; for example, white citizens received R 218; Coloureds and Indians received R 167 and the Black majority received R 117 (Patel, 2005).

Furthermore, the apartheid government formed an immense bureaucratic structure to legitimise the radical philosophy of distinct growth (Mahaj, 2019). To this end, 18 social welfare service departments and homelands were created to deliver social facilities and welfare services. Correspondingly, the departments of education, home affairs, and health were established at gigantic costs to the management of the government (Chisholm, 2012; Chipps and Jarvis, 2016). This tact by the government had key economic insinuations, which plunged the apartheid government into a massive liability. It can be contended that the apartheid government was not only accountable for the underdevelopment of most black South African citizens (White, Blaauw, *et al.*, 2020), but also for their current inability to access most social facilities conveniently.

Numerous laws were enforced to ensure a distinct progress of races in South Africa (Mahaj, 2019). The Department of Social Welfare and Pensions Circular 66 of 1966 is a suitable example (Chisholm, 2012). This department instructed social facilities and welfare groups to implement apartheid rules that would perpetuate disparate and distinct facilities for diverse race clusters established by the apartheid regime. Moreover, according to this Act, social labours could only render services to their own race groups whereas distinct panels of administration had to serve numerous race groups (Gibson, 2003). This racial regulation deliberately ensured that the apartheid regime existed mainly for the benefit and preservation of white people (Chisholm, 2012; Chipps and Jarvis, 2016). The effects of this regulation are still notable in the current gap between the rich and the poor in South Africa (Chipps and Jarvis, 2016).

The enactment of the National Welfare Act 100 of 1978 indelibly informed the creation of local well-being panels grounded beside racial outlines (Chisholm, 2012). A multi-racial nationwide

well-being panel was also created to guide the management of well-being apprehensions (Chipps and Jarvis, 2016). Black social workers could not render efficient services to their own race due to apartheid laws founded upon ethnic discrimination, which resulted in the well-being of black people being at a disadvantage even post-apartheid (Gibson, 2003; Mahaj, 2019). The prejudicial allocation of social facilities and welfare service societies, homes, and social welfare resources predominantly to white people meant that black people would on the contrary settle either for poor or no social facilities at all (Mahaj, 2019). Furthermore, the National Welfare Act 100 of 1978 Act provided an income for the organisation to manage and adjust global donor funding, which ensured that certain parties, i.e. white-led parties, had a backup of facilities for their (white) groups (Chisholm, 2012). However, some non-profit organisations received global backup for attempting to address the dilemma constantly faced by underprivileged societies (Gibson, 2003).

The Population Registration Act, 1950 categorised all South Africans into 1 of the 4 ethnic groups based on appearance, recognised origin, socio-economic rank and social lifestyle (Mahaj, 2019). Places of residence were determined by ethnic categorisation. Between 1960 and 1983, about 3.5 million Africans were detached from their homelands and forced into separated neighbourhoods because of apartheid legislatures, with the chief among them being forced removals (Chipps and Jarvis, 2016). These removals were intended to restrict the black population to 10 designated ethnic motherlands, also known as Bantustans, 4 of which became technically self-governing states. The individuals that were forcefully removed ultimately lost their South African nationality after being placed at the Bantustans (Chipps and Jarvis, 2016).

Apartheid glimmered a substantial world-wide and national antagonism, after some of the greatest and powerful worldwide communal activities of the 20th century (Gibson, 2003). The United Nations brought about a widespread arms and trade restriction to South Africa (Mahaj, 2019). During the 1970s and 1980s, an internal confrontation of apartheid became progressively aggressive, encouraging brutal restrictions by the National Party's management and prolonged denominational viciousness that left thousands either dead or in detention (Chisholm, 2012; Chipps and Jarvis, 2016). Some reforms of the apartheid system were commenced, including allowing for Indian and Coloured political activism in the assembly, but these procedures botched to mollify most activist groups (Chipps and Jarvis, 2016).
